WIRELESS EMERGENCY WARNING SYSTEMS DESIGN AND IMPLEMENTATION

A THESIS SUBMITTED TO THE NEAR EAST UNIVERSITY

BY

MEHMET UGURLU

IN PARTIAL FULFILLMENT OF THE REQUIREMENT FOR THE DEGREE OF
MASTER SCIENCE
IN
THE DEPARTMENT OF ELECTRIC AND ELECTRONIC ENGINEERING

MAY 2003

"Communities that do not develop information and technology, which is the immediate product of information, lose their independence and as its consequence lose their happiness. "

"Bilgi ve onun ürünü olan teknolojiyi üretmeyen toplumlar bağımsızlıklarını dolayısıyla mutluluklarım yitirirler."

Scientist Temel, who is traditional character in Turkish jokes, is invited to the archeology conference.The American scientist start to tell " we went 25 metres down in our excavations in our hometown and found phone cables. Thus, our ancestors used phone many centuries ago ".Now it is Turkey's turn and Temel begins telling "we went 50 metres down in our excavations in our hometown as well but we didn't find anything. Thus our ancestors used *wireless* phone(GSM) many centuries ago"

Approval of the Graduate School of the Near East University

Director

I certify that this thesis satisfies all the requirements as a thesis

for the degree of Master of Science.

Electric&Electronic Engineer
Head of Department

This is to certify that we have read this thesis and that in our

opinion it is fully adequate, in scope and quality, as a thesis for

the degree of Master of Science.

ABSTRACT

WIRELESS EMERGENCY WARNING SYSTEMS

DESIGN AND IMPLEMENTATION

MEHMET UGURLU

M.Sc.,Department of Electric and Electronic

Supervisor: Prof.Dr.Fahreddin Mamedov

Co-Superviser: Prof.Dr.Şenol Bektaş

May2003

The life is not only becoming easy, but gaining speed also by technological improvements. Especially the wireless technology has become an indispensable factor in communication in which a great advance has been established in last several years. In many fields, people are racing with time and requiring correct information, in appropriate location and time. Administrations are making a loss, since they can't reach information instantly when they need. Mobile phones, Internet, fax-data communication, SMS (short message service) and WAP are becoming widespread in popular fields rapidly. By widening in usage, the GSM (Global System for Mobile Communications) technology is taking part in industrial organizations, hotels, financial associations, residences, media and shooping centers.

The "Wews System"(wireless emergency warning system) that was developed in this project, provides an SMS communication from PC's fed by sensor signals to mobile phones of the users. The messages include information about failures, dangerous situations and production processes in industrial organizations, residences and shopping centers, firstly. In this study, content information is given on usage of sensors, technical features, montage, electrical and logical connections, pc ports and low level programming and GSM network infrastructure.

Keywords: sensors,wews,pc ports,sms,gsm

Ortak Tez Yöneticisi: Prof:Dr.Şenol Bektaş

Mayıs 2003

Teknolojinin ilerlemesiyle beraber hayat daha kolaylaşmakta, ancak bir o kadar da hızlanmaktadır. Son birkaç yılda dünyada büyük ilerleme kaydedilen haberleşme alanında, özellikle wireless communication hayatın vazgeçilmez bir unsuru olmuştur. Bir çok alanda insanlar zamanla yarışır hale gelmiş olup, doğru bilgi yerinde ve zamanında kullanıldığında önemli olmakta, aksi halde önemini yitirmektedir. Doğru bilginin yerine zamanında ulaşmamasından dolayı işletmeler maddi zararlara uğrayabilmektedir. Cep telefonlarının kullanımı internet, faks-data iletişimi, SMS (short Message Service), WAP gibi popüler alanlarda hızla yaygınlaşmaktadır. Uygulama alanlarının genişlemesi ile GSM (Global System for Mobile Communications) teknolojisi endüstriyel tesisler,oteller,finanas kurumlarında,konutlarda,medya kuruluşlarında,alışveriş merkezlerinde yer almaya başlamıştır.

Bu çalışmada gerçekleştirilen WEWS sistemi İle başta endüstriyel sistemler olmak üzere, alışveriş merkezleri, konutlar, oteller , mağazalar vb yerlerde meydana gelen arıza veya tehlike durumu, işletmelerde gerekli üretim bilgileri gibi bilgiler, PC'ye bağlı bulunan sensörlerden alınan sinyallerin değerlendirilerek wireless network aracılığıyla kullanıcıların cep telefonlarına SMS olarak iletilebilmektedir. Bu çalışmada ayrıca, Sensorlerin kullanım alanları, teknik özellikleri, montajı ve elektriksel,mantıksal bağlantıları Bilgisayar Portlarının teknik özellikleri,programlanması, elektriksel,mantıksal bağlantıları GSM network hakkında bilgi verilmiştir.

Anahtar Kelimeler: sensors,wews,ports,sms,gsm

ACKNOWLEDGMENTS

I express sincere appreciation to Prof.Dr.Fahreddin Maınedov for his guidence and insight thoroughout the research. Thanks go to the other faculty members, Prof.Dr.Şenol Bektaş for his suggestions and comments and thanks to Research Assistant Aylin Aytaç for her help.Also special thanks to my colleagues.

CHAPTERl

SENSORS TECHNOLOGY

1.1 INTRODUCTION

Microsensors have become an essential element of process control and analytical measurement systems, finding countless applications in, for example, industrial monitoring, factory automation, the automotive industry, transportation, telecommunications, computers and robotics, environmental monitoring, health care, and agriculture; in other words, in almost all spheres of our life. The main driving force behind this progress comes from the evolution in the signal processing. With the development of microprocessors and application-specific integrated circuits (1C), signal processing has become cheap, accurate, and reliable---and it increased the intelligence of electronic equipment. In the early 1980s a comparison in performance/ price ratio between microprocessors and sensors showed that sensors were behind. This stimulated research in the sensor area, and soon the race was on to develop sensor technology and new devices. New products and companies have emerged from this effort, stimulating further advances of microsensors. Application of sensors brings new dimensions to products in the form of convenience, energy savings, and safety. Today, we are witnessing an explosion of sensor applications. Sensors can be found in many products, such as microwave and gas ovens, refrigerators, dishwashers, dryers, carpet cleaners, air conditioners, tape recorders, TV and stereo sets, compact and videodisc players. And this is just a beginning.

1.2 SENSOR CLASSIFICATION

Sensing the real world requires dealing with physical and chemical quantities that are diverse in nature. From the measurement point of view, all physical and chemical quantities (measurands) can be divided into six signal domains.

The thermal signal domain: the most common signals are temperature, heat, and heat flow.

The mechanical signal domain: the most common signals are force, pressure, velocity, acceleration, and position.

The chemical signal domain: the signals are the internal quantities of the matter such as concentration of a certain material, composition, or reaction rate.

The magnetic signal domain: the most common signals are magnetic field intensity, flux density, and magnetization.

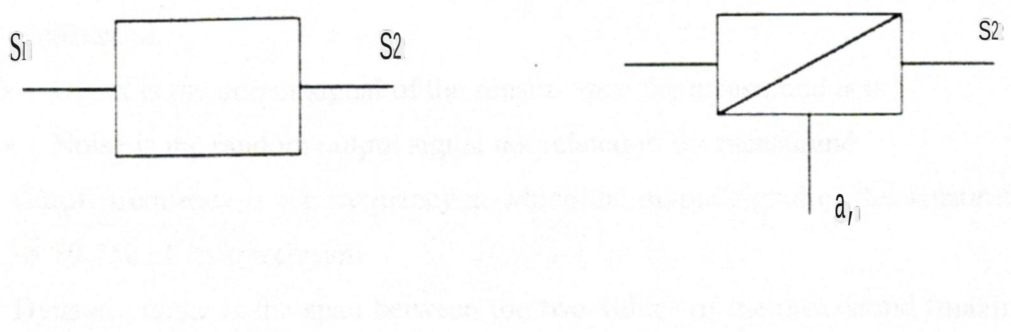
The radiant signal domain: the signals are quantities of the electromagnetic waves such as intensity, wavelength, polarization, and phase.

The electrical signal domain: the most common signals are voltage, current, and charge.

As mentioned, sensors convert nonelectrical physical or chemical quantities into electrical signals. It should be also noted that the principle of operation of a particular sensor is dependent on the type of physical quantity it is designed to sense. Therefore, it is no surprise that a general classification of sensors follows the classification of physical quantities. Accordingly, sensors are classified as thermal, mechanical, chemical, magnetic, and radiant.

There is also a classification of sensors based on whether they use an auxiliary energy source or not. Sensors that generate an electrical output signal without an auxiliary energy source are called *self-generating* or *passive*. An example of this type of sensor is a thermocouple. Sensors that generate an electrical output signal with the help of an auxiliary energy source are called *modulating* or *active*. Figure 1.1 shows symbolic presentations of self-generating and modulating sensors. Here, *Si* represents the input signal, *sı* is the output signal, and a, is the auxiliary energy source. In modulating sensors, the auxiliary energy serves as a main source for the output signal, and the measured physical quantity modulates it. This class of sensors includes magnetotransistors and phototransistors. Modulating sensors are the best choice for the measurement of weak signals.

In addition to the preceding classifications, there are many others based on some common features. A good example is automotive, where



A B

Figure 1.1 Symbolic presentation of self-generating and modulating sensor: (a) self-generating sensor; (b) modulating sensor, wheres, is the input signal, *s₁* is the output signal, *a,* is the auxiliary energy source.

the common feature is the application in automobiles for engine and vehicle control. A curious reader can find more information about the classification of sensors in a recently published book on silicon sensors

1.3 SENSOR PARAMETERS

Performance of sensors, like other electronic devices, is described by parameters.

- Absolute sensitivity is the ratio of the change of the output signal to the change of the measurand (physical or chemical quantity).
- Relative sensitivity is the ratio of a change of the output signal to a change in the measurand normalized by the value of the output signal when the measurand is 0.
- Cross sensitivity is the change of the output signal caused by more than one measurand.
- Direction dependent sensitivity is a dependence of sensitivity on the angle be tween the measurand and the sensor.
- Resolution is the smallest detectable change in the measurand that can cause a change of the output signal.
- Accuracy is the ratio of the maximum error of the output signal to the full-scale output signal expressed in a percentage.
- Linearity error is the maximum deviation of the calibration curve of the output signal from the best fitted straight line that describes the output signal.
- Hysteresis is a lack of the sensor's capability to show the same output signal at a given value of measurand regardless of the direction of the change in the

measurand.

- Offset is the output signal of the sensor when the measurand is 0.
- Noise is the random output signal not related to the measurand.

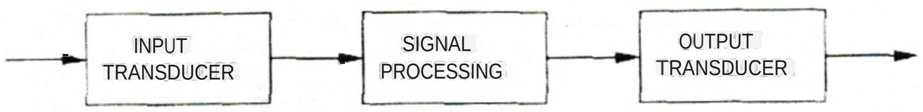
- Cutoff frequency is the frequency at which the output signal of the sensor drops to 70.7% of its maximum.
- Dynamic range is the span between the two values of the measurand (maximum and minimum) that can be measured by sensor.
- Operating temperature range is the range of temperature over which the output signal of the sensor remains within the specified error.

It should be pointed out that in addition to these common parameters, other parameters are often used to describe other unique properties of sensors.

1.4 A SEAMLESS SENSOR SYSTEM

Sensing systems are generally used for process control and measurement instrumentation. A simple block diagram of a sensing system is shown in Figure 2 As can be seen, the term *transducer* is used for both the input and the output blocks of the sensing system. The role of the input transducer is to get information from the real world about a physical or chemical quantity; in other words, to "sense the world." This is the reason why input transducers are commonly called *sensors*. Often the electrical signals generated by sensors are weak and have to be amplified or processed in some way. This is done by the signal processing part of the sensing system. Finally, the role of the output transducer is to convert an electrical signal into a form acceptable for our senses or to initiate some "action," for example, opening or closing a valve. For this reason, output transducers are often called *actuators*. A simple block diagram of the sensing system, as just described, helps to grasp the basic concept of sensing, but it really does not tell the whole story.

Much has been written about the phenomenal development of microelectronics and the strong influence of microprocessors and other integrated circuits on sensing systems. Figure 3 shows a typical sensing system composed of the many devices



Fiaure 1. 2 Simple block diagram of the sensing system.

of modem microelectronics . Following the signal path in Figure 3, one can see that the electrical signals created by sensors are amplified, converted to digital form, and transferred to a microprocessor. The microprocessor also controls a variety of actuators through the interface circuits, where the signals are converted back to analog form and used to drive the actuators. The entire sensing system thus can form a closed control loop.

Also, the microprocessor may communicate with a higher level control computer, making the sensing system, shown in Figure 1.3, part of a larger system. Currently, the type of sensing system shown in Figure 1.3 is spatially distributed and made of separate functional blocks. Point-to-point wiring is typically used for the electrical connection between the blocks. Many experts expect in the future that such sensing systems will be integrated into a single chip, forming a "smart" sensor or "seamless" sensor system, where boundaries between the functional blocks will not be apparent.

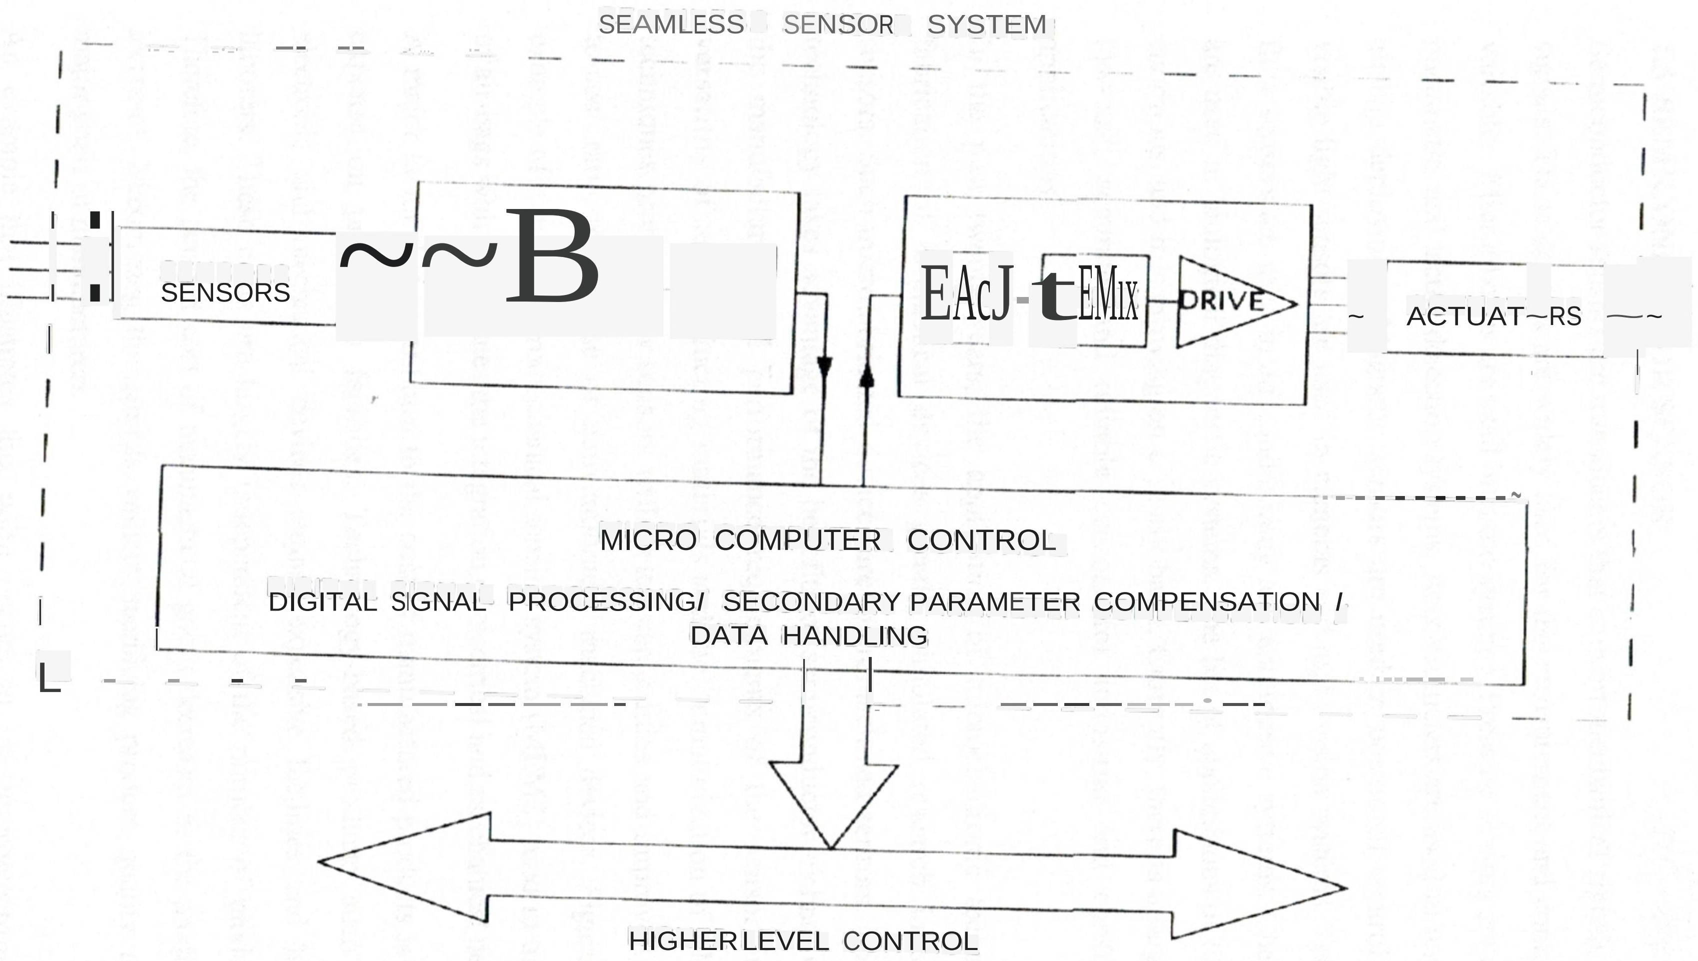


Figure 1.5 Seamless sensor system on the chip.

1.5 SEMICONDUCTOR SENSOR

Semiconductor sensors are transducers that convert mechanical signals into electrical signals. These devices are widely used for the measurement and control of physical variables. Microphones are used in audio systems. Pressure sensors are used in fluidic, pneumatic, and tactile detection systems. Accelerometers are used in navigational and air-bag deployment. Magnetic sensors are used in positional control. Infrared and visible light sensors are used in cameras and night-vision systems. Temperature and flow sensors are used in air conditioning and automotive systems. Chemical sensors are used in biological diagnostic systems. The list of applications of these devices is enormous, and it is growing on a yearly basis. Currently, there is a large demand for low-cost, accurate, and reliable sensors for industrial and consumer product applications.

In the past twenty years, the application of microelectronic technology to the fabrication of mechanical devices greatly stimulated research in semiconductor sensors. Such microfabricated devices are micromachined sensors. Micromachining technology takes advantage of the benefits of semiconductor technology to address the manufacturing and performance requirements of the sensor industry. The versatility of semiconducting materials and the miniaturization of VLSI patterning techniques promise new sensors with better capabilities and improved performance-to-cost ratio over those of conventionally machined devices. Figure 4 shows an example of a microelectromechanicalsensing system (MEMS) used in the deployment of air-bags which illustrates the integration of electrical and mechanical devices.

A major factor that contributes to the cost of manufactured products is the overhead expense on production facilities. Technology-based products such as precision electronic and mechanical devices require expensive facilities and highly skilled laborers. These costs are largely independent of the number of products produced. Therefore, the per-unit cost of manufactured goods decreases as the production volume increases. Maximizing throughputs without sacrificing product quality is one of the major goals of manufacturers.

An example that illustrates this point occurs in the microelectronics industry. Integrated-circuit technology allows thousands of electronic circuits to be batch-fabricated simultaneously through a single pass of processing sequences. Batch-fabrication of microelectronic circuits was made possible through the invention of planar technology. In the planar manufacturing process, three-dimensional devices are built on a wafer substrate using stacked layers of planar materials with different but coordinated two-dimensional patterns.

Analog Devices' ADXL-50, the industry's first surface micromachined accelerometer, includes signal conditioning on chip.

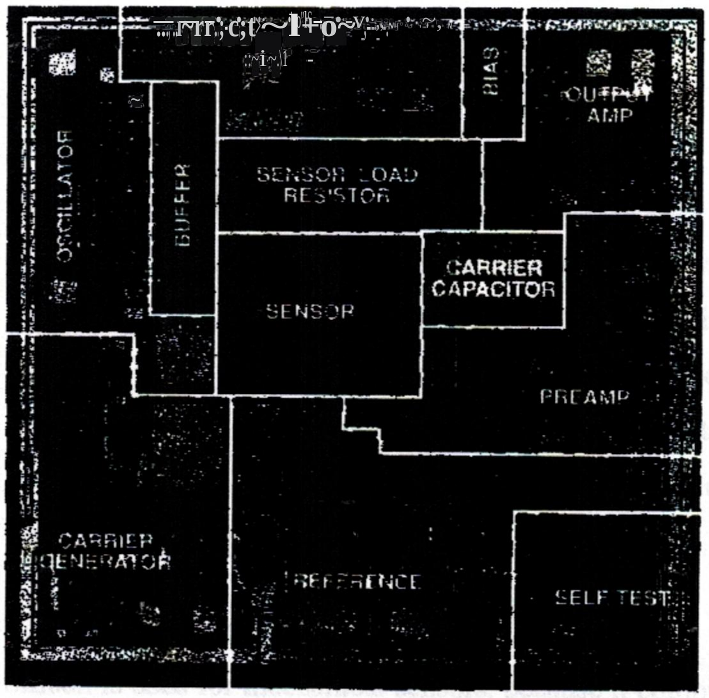

Fig 1.4 State of the art surface micromachined accelerometer that integrates micro-mechanical sensors with BICMOS technology. (Courtesy of Analog Devices.)

By optically repeating the patterns on the wafer, many units are fabricated with just one pass of the process . Micromachined sensors benefit from the same planar manufacturing processes.

Because sensors receptive to different physical variables are structurally different, in general, there is no single technology that allows for the fabrication of a wide variety of sensors. However, there are two major classifications of microsensor technologies. *Bulk-micromachined* sensors are primarily made by the accurate machining of a relatively thick substrate. *Swface-micrimachined* sensors are primarily constructed from stacked thin films. Both technologies use materials and processes borrowed from VLSI technology. The three processes of deposition, lithography, and etching are sufficient to construct a wide variety of mechanical structures required for specific sensors. A fundamental sensor-fabrication problem is the development of a suitable fabrication-process sequence of these basic machining steps that define the desired shape and function of the device.

1.6 SENSOR TYPES

a. Acoustic sensors

Acoustic sensors are devices that employ elastic waves at frequencies in the megahertz to low gigahertz range to measure physical, chemical, or biological quantities. Their high sensitivity makes these devices particularly attractive for chemical vapor and gas sensing. In many cases, the output of these sensors is a frequency, which can be measured simply and accurately with an electronic counter. With proper design, these sensors can be quite stable, permitting a\ large dynamic range to be realized.

b. Mechanical Semiconductor Sensors

Silicon is used for mechanical sensors, because it combines well-established electronic properties with excellent mechanical properties. Other advantages of silicon include drastically reduced dimensions and mass, batch fabrication and easy interfacing or even integration with electronic circuits and microprocessors. Interest in the mechanical properties of silicon and its use for sensors started with the discovery of its piezoresistivity. Toe first mechanical sensor was the piezoresistive pressure sensor, but since the development of this sensor, a very wide variety of sensors has been conceived and produced.

c, Magnetic sensor

A magnetic sensor is capable of converting a magnetic field into a useful electrical / signal. A magnetic sensor is also needed whenever a nonmagnetic signal is / detected by means of an intermediaiy conversion into a magnetic signal in a so-called tandem transducer. Examples are the detection of a current through its magnetic field or the mechanical displacement of a magnet. Thus, we can distinguish two groups of direct and indirect magnetic-sensor applications.[3]

In *direct* applications, the magnetic sensor is part of a magnetometer. Examplesare the measurementof the geomagneticfield, the reading of magnetic data storage media, the identification of magnetic patterns in cards or banknotes, and the control of magnetic apparatus.

In *indirect* applications, the magnetic field is used as an intermediary carrier for detecting nonmagnetic signals. Examples are potential-free current detection for overload protection, integrated watt-hour meters, and contactless linear or angular position, displacement,or velocitydetectionusing a permanentmagnet

These applications require the detection of magnetic fields in the micro- and milliteslarange, which can be achievedby integratedsemiconductorsensors.

Contactless switching for keyboards or collectorless DC motor control, displacement detection for proximity switches or crankshaft position sensors, and current detection seem to comprise most of the large-scale applications of magnetic sensors. It is for these large-scale applications that inexpensive batch-fabricated semiconductor magnetic sensors are highly desirable. It is unlikely that integrated silicon magnetic sensors will ever replace nuclear magnetic resonance (NMR) magnetometry with resolution in the nanotesla region, let alone the superconducting quantum interference devices (SQUID) resolving picotesla fields occurring in biomagnetometıy.

With respect to the above ranges of magnetic resolution, we recall the following magnetic units. As a measure for the magnetic field strength *H* we use the related magnetic induction *B*, whose unit is 1 tesla = 1 V-s/m^2. This is the inverse of the unit of carrier mobility, namely 1 m^{2}N-s = 10^{4}cm^{2}N-s=l T. The product of magnetic induction and mobility is a dimensionless number which controls the strength of the galvanomagnetic effects.

Semiconductor magnetic sensors including integrated silicon and GaAs • sensors are useful in the range between 1 /iT and 1 T. Here are some examples II of magnetic induction within that range:

- geomagnetic field 30-60 /*T
- magnetic storage media about 1 mT
- permanent magnets in switches 5-100 mT
- conductor carrying a 10 A current 1 mT
- superconducting coils 10-20 T

d. Radiationsensors

Radiation sensors_transform incident radiant signals into standard electrical output signals to be used for data collection,processing and storage.Radiant signals can be categorized into one of the following types: electromagnetic, neutrons, fast electrons, or heavy-charge particles. Electromagnetic radiation and neutrons are uncharged, while fast electrons and heavy-charged particles are charged-particulate radiation.All radiant signals originate in atomic or nuclear processes, and similar techniques are used for their detection

e. Thermal sensors

The operation of thermal sensors generally can be described in three steps. In the first step the non-thermal quantity is transduced into a thermal quantity by either transducing the power of the non-thermal quantity directly into a heat flow (the self-generating sensors), or by exerting influence by the non-thermal signal on a heat-flow generated by the sensor itself (the modulating sensors). In the second step, the heat flow in the sensor is converted into a temperature difference by means of a thermal resistance. In silicon sensors, micromachining has proved to be a powerful tool for obtaining optimized thermal structures. Closed membranes, cantilever beams and bridges, and floating membranes are often encountered structures in which thermal resistances ahd parallel conductances can be defined veıy accurately in a simple way. In the third step, the temperature difference is transduced into an electrical signal. The main elements used for this step are transistors or resistors that measure the absolute temperature and are suited for smart sensors, and thermocouples which are interesting for measuring temperature differences, as they can do this without offset and will not spoil the offsetless character of self-generating sensors.

f. Chemical sensors

All the forms of semiconductor chemical sensors have one major problem. In order to detect the chemical species of interest, the sensors must be exposed, unprotected, to the ambient solution or gas. It is difficult to make them reversibly reactive to the gases of interest and nonreactive with respect to all other possible chemical species that may appear in the atmosphere or liquid. Fortunately, in most cases, the form of interference is known and an ideal sensor is not required. For example, the degrading effect of H_2S or Cl_2 on some sensors is no problem if the user is sure these particular species will not be present.

Sensors from semiconducting metal oxides have the desired feature of low cost, good sensitivity, and convenient form of response (a simple change in resistance). These features have made, and undoubtedly will continue to make, these sensors popular. However, the sensors have problems in reproducibility, stability and selectivity. Every improvement in these aspects will undoubtedly increase the usage of the devices.

g. Biosensor

Biosensors are a special class of chemical sensors that take advantage of the high selectivity and sensitivity of biologically active materials. This high selectivity and sensitivity of the biological material is a result of millions of years of evolution of life on earth, since much of the communication among /biological organisms is based on chemical signals, whether the senses of smell and taste, or immunological reactions, or pheromones, or "hunting" of single-celled organisms. Even the senses of vision, hearing, and touch are transmitted by chemical communication through the nervous system. These communication processes can be considered to be "bio-recognition" processes. Thus, the potential to use these bio-recognition processes as inputs to a sensor is apparent. The diversity of life is reflected in the large variety of biosensors, since there are biological chemicals, organelles, cells, tissues, and organisms that react to everything from small inorganic molecules, such as oxygen, to large, complicatedproteins and carbohydrates.

CHAPTER2

PORTS COMMINICATIONS

2.1 PARALLEL PORT

DB25 (Figure 2.I) connector with an 8 bit data bus (Pin 2-7) which is more popularly used for computer printers while is still used for other devices.

The standard length of Printer Parallel cables is a maximum of I5 feet although there are 50 foot cables it is not recommended that these cables be used as it can create poor connection and data signals.

2.2 TYPES OF PARALLEL PORTS

Unidirectional - 4-bit standard port which by factory default did not have the capability of transferring data both ways.

Bi-directional - 8-bit standard port which was released with the introduction of the PS/2 port in 1987 by IBM and are still found in computers today. The Bi-directional port is cable of sending 8-bits input and output. Today on multifunction printers this port can be referred to as a bi-directional, Centronics, PS/2 type or standard port.

EPP - The Enhanced Parallel Port (EPP) was developed in I99 I by Intel, Xircom and Zenith Data Systems and operates close to ISA bus speed and can achieve transfer rates up to 1 to 2MB/sec of data.

EPP version I. 7 released in 1992 and later adapted into the IEEE 1284 standard. All additional features are adapted into the IEEE standard.

EPP version 1.9 never existed.

ECP - The Enhanced Capabilities Port (ECP) was developed by Microsoft and Hewlett-Packard and announced in 1992 is an additional enhanced Parallel port. Unfortunately with ECP it requires an additional DMA channel which can cause resource conflicts.

2.3 PARALLELPORTDEVICES

Printer - The most common use for the Parallel port.

Scanner - Another commonly used parallel device is the Parallel scanner. Parallel scanners are a popular alternative to SCSI scanners because of how easy they are to to install.

External Drives - Another popular use of the Parallel ports are external drives such as the,sensors and other devices which can be easily removed from one computer and placed onto another.

Port Name	Adress(Hex)	(Hex)
DATA(D)	378	378

Pin24	-Data Bit 6 Return (GND)
Pin25	~Data Bit 7 Return (GND)

The following is an explanation of each of the above purposes.

Pint = Data acknowledgement when the signal is low.
Pin 2 - 9 = Data transfer pins.
Pin 10 = Acknowledge that the data has finished processing and when the signal is high indicates ready for more.
Pin 11 = When the signal goes high indicate that the printer has accepted the data and is processing it. Once this signal goes low and Pin 10 goes high will accept additional data.
Pin 12 = Printer paper jam when signal is high or no signal if printer jam.
Pin 13 = When high signal printer is indicating that it is on-line and ready to print.
Pin 14 = When low signal PC has indicated that the printer inset a line feed after each line.
Pin 15 = Printer sends data to the computer telling it that an error has occurred.
Pin 16 = When low signal PC has requested that the printer initiate a internal reset.
Pin 17 = When low signal the PC has selected the printer and should in return prepare for data being sent.
Pin 18 - 25 = Ground.

2.4 SERIAL PORT

The serial port is an Asynchronous port which transmits one bit of data at a time, usually connecting to the UART Chip. Serial Ports are commonly found on the majority of PC Compatible computers. Usually referred to as a DB9 or DB25 connection both of which adhere to the RS-232c interface standard and defined in ISO 2110 and ISO 4902. D represents the shape of the connector if placed vertically as shown in the below illustrations. The number 9 / 25 indicating the number of pins found on the connector. DB9 Serial connections are now commonly found on modem PC's where DB25 is commonly found on older computers.

2.5 SERIAL PORT DEVICES

The following is a listing of various hardware components which can be purchased and used with your Serial port.

Mouse - One of the most commonly used devices for serial ports, usually used with computers with no PS/2 Ports or laptop computers.

Modem -Another commonly used device for serial ports. Used commonly with older computers however is also commonly used with computers for its ease of use.

Network- One of the original uses of the serial port, which allowed two computers to connect together and allow large files to be transferred between the two.

Printer - Today is not commonly used device for serial ports (not applicable to the DB25 or Parallel Port). However was frequently used with older printers and plotters.

External Drives - In this project we use celuler phone.

2.6 **DB9 INFORMATION**

In the illustration below you can notice several factors to help correctly identify the DB9 Serial connection. First you will notice that the DB9 connection has 9 pins which are each described in the below chart. The illustration below is an example of the female serial connector which would usually be located on the connector that would connect to the computer. each serial connector generally has two screws measuring .3 cm to allow the serial connection to be securely connected to the back of the computer.

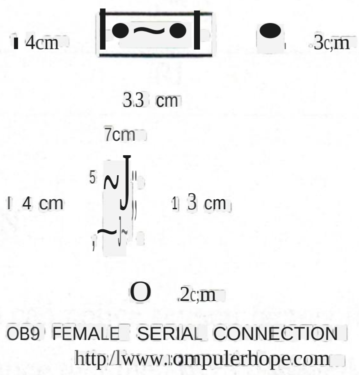

Figure 2.2 DB9 Femail Serial connection

Identifying:

The DB9 serial connection is identified first by its 9 pins.
The DB9 is shaped like a D.
The DB9 will generally be a male connector on the back of the computer.

The following is a listing of each of the pins located on the DB9 connector and what each of these pins are for.

PiN	PURPOSE	sIGNALN~
Pin 1	Data Carrier Detect	DCD
Pin2	Received Data	RxData
Pin 3	Transmitted Data	TxData
Pin4	Data Terminal Ready	DTR
Pin 5	Signal Ground	Gnd
Pin 6	Data Set Ready	DSR
Pin 7	Request To Send	RTS
Pin 8	Clear To Send	cTS
Pin 9	Ring Indicator	ru

2.7 DB25 INFORMATION

In the illustration below you can notice several factors to help correctly identify the DB25 port. First you will notice that the DB25 connection has 25 pins which are each illustrated in the below chart.

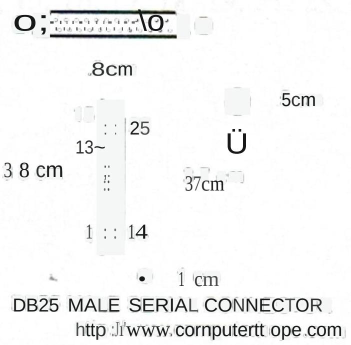

Figure 2.3 Mail Serial Connection

Identifying:

The DB25 serial connection is identified first by its 25 pins.

The DB25 is shaped like a D.

The DB25 is generally be a male connector on the back of the computer.

DB25	Signal Name
8	Data Carrier Detect (DCD)
3	Reive Data (RxD)
2	Transmite Data (TxD)
20	Data Terminal Ready (DTR)
7	Signal Ground (GND)
6	Data Set Ready (DSR)
4	Request to Sent (RTS)
5	Clear to Sent (CTS)
22	Ring Indicator (RI)

Note: I, 9, 10, 11, 12, 13, I4, 15, 16, 17, I8, I9, 21, 23, 24 and 25 pins are not use in DB25.

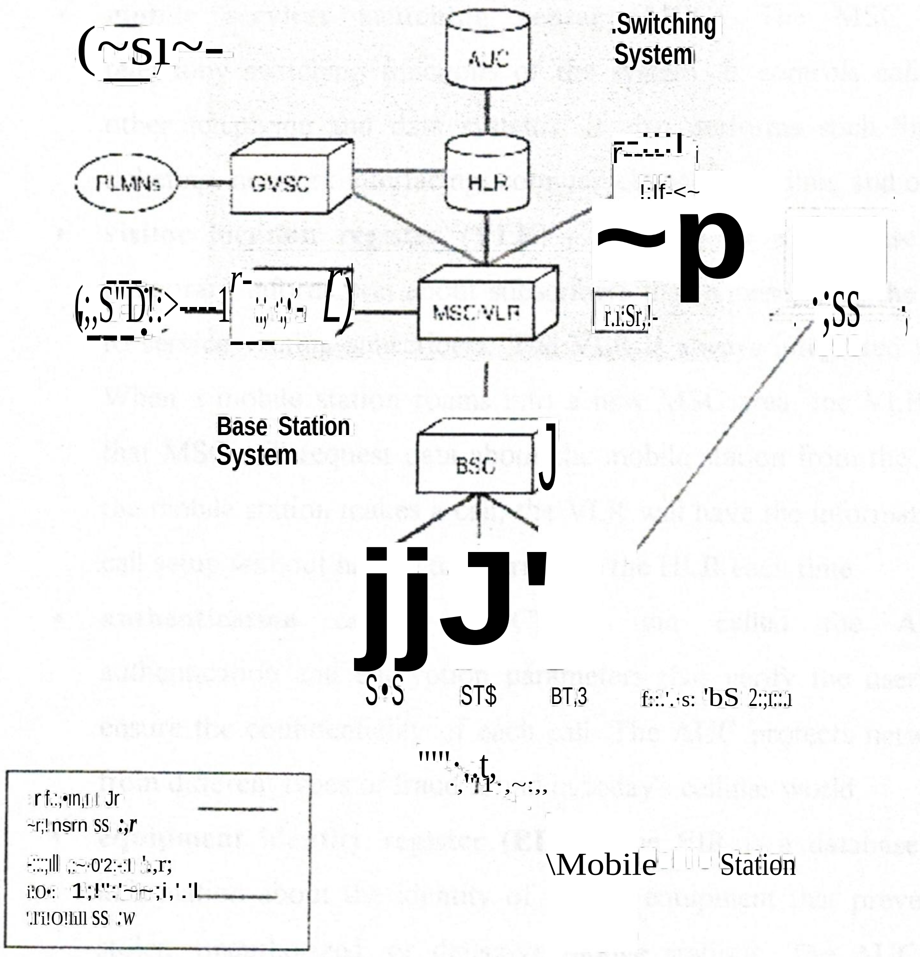
CHAPTER4

GLOBAL SYSTEM FOR MOBILE NETWORK

4.1 The GSM Network

GSM provides recommendations, not requirements. The GSM specifications define the functions and interface requirements in detail but do not address the hardware. The reason for this is to limit the designers as little as possible but still to make it possible for the operators to buy equipment from different suppliers. The GSM network is divided into three major systems: the switching system (SS), the base station system (BSS), and the operation and support system (OSS). The basic GSM network elements are shown in *Figure 4.1.*

Figure 4.1 GSM Network Elements



4.2 The Switching System

The switching system (SS) is responsible for performing call processing and subscriber-related functions. The switching system includes the following functional units.

- home location register (HLR)-The HLR is a database used for storage and management of subscriptions. The HLR is considered the most important database, as it stores permanent data about subscribers, including a subscriber's service profile, location information, and activity status. When an individual buys a subscription from one of the PCS operators, he or she is registered in the HLR of that operator.
- mobile services switching center (MSC)-The MSC performs the telephony switching functions of the system. It controls calls to and from other telephone and data systems. It also performs such functions as toll ticketing, network interfacing, common channel signaling, and others.
- visitor location register (VLR)-The VLR is a database that contains temporary information about subscribers that is needed by the MSC in order to service visiting subscribers. The VLR is always integrated with the MSC. When a mobile station roams into a new MSC area, the VLR connected to that MSC will request data about the mobile station from the HLR. Later, if the mobile station makes a call, the VLR will have the information needed for call setup without having to interrogate the HLR each time.
- authentication center (AUC)-A unit called the AUC provides authentication and encryption parameters that verify the user's identity and ensure the confidentiality of each call. The AUC protects network operators from different types of fraud found in today's cellular world.
- equipment identity register (EIR)-The EIR is a database that contains information about the identity of mobile equipment that prevents calls from stolen, unauthorized, or defective mobile stations. The AUC and EIR are implemented as stand-alone nodes or as a combined AUC/EIR node.

4.3 The Base Station System (BSS)

All radio-related functions are performed in the BSS, which consists of base station controllers (BSCs) and the base transceiver stations (BTSs).

- BSC-The BSC provides all the control functions and physical links between the MSC and BTS. It is a high-capacity switch that provides functions such as handover, cell configuration data, and control of radio frequency (RF) power levels in base transceiver stations. A number ofBSCs are served by an MSC.
- BTS-The BTS handles the radio interface to the mobile station. The BTS is the radio equipment (transceivers and antennas) needed to service each cell in the network. A group of BTSs are controlled by a BSC.

4.4 The Operation and Support System

The operations and maintenance center (OMC) is connected to all equipment in the switching system and to the BSC. The implementation of OMC is called the operation and support system (OSS). The OSS is the functional entity from which the network operator monitors and controls the system. The purpose of OSS is to offer the customer cost-effective support for centralized, regional, and local operational and maintenance activities that are required for a GSM network. An important function of OSS is to provide a network overview and support the maintenance activities of different operation and maintenance organizations.

4.5 Additional Functional Elements

Other functional elements shown in *Figure 2* are as follows:

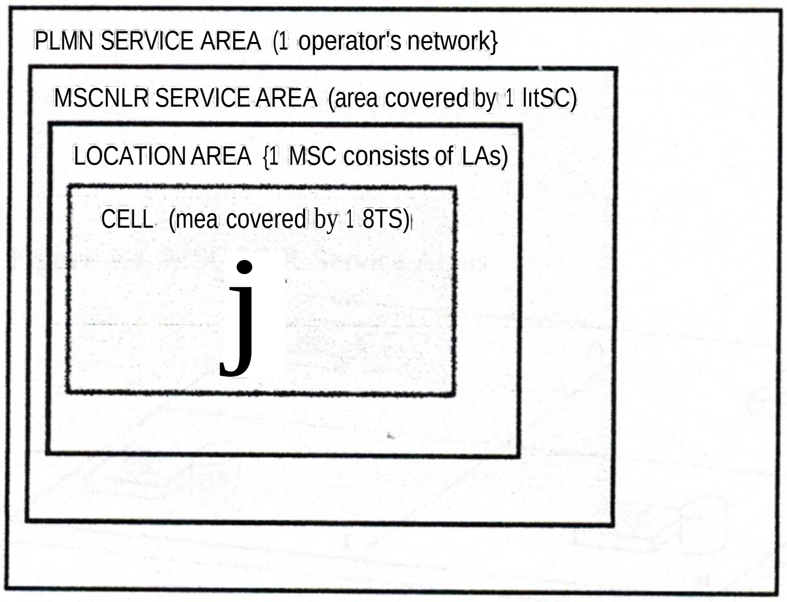
- message center (MXE)-The MXE is a node that provides integrated voice, fax, and data messaging. Specifically, the MXE handles short message service, cell broadcast, voice mail, fax mail, e-mail, and notification.
- mobile service node (MSN)-The MSN is the node that handles the mobile intelligent network (IN) services.

- gateway mobile services switching center (GMSC)-A gateway is a node used to interconnect two networks. The gateway is often implemented in an MSC. The MSC is then referred to as the GMSC.
- GSM interworking unit (GIWU)-The GIWU consists of both hardware and software that provides an interface to various networks for data communications. Through the GIWU, users can alternate between speech and data during the same call. The GIWU hardware equipment is physically located at the MSC/VLR.

4.6 GSM Network Areas

The GSM network is made up of geographic areas. As shown in *Figure 4.2*, these areas include cells, location areas (LAs), MSC/VLR service areas, and public land mobile network (PLMN) areas.

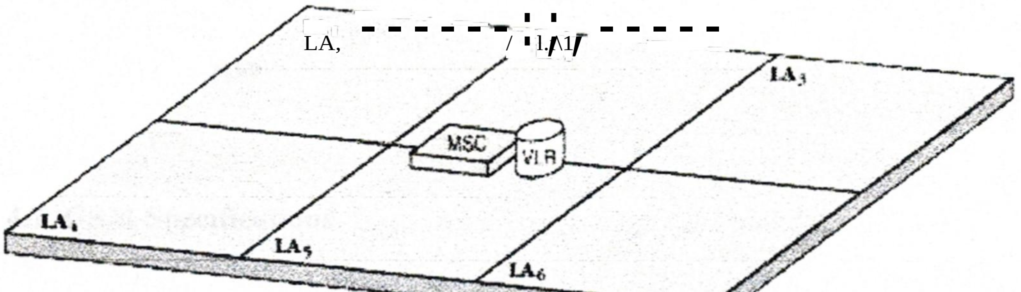
Figure 4.2 Network Areas



PLMN SERVICE AREA (1 operator's network}
MSCNLR SERVICE AREA (area covered by 1 lItSC)
LOCATION AREA {1 MSC consists of LAs)
CELL (mea covered by 1 8TS)
j

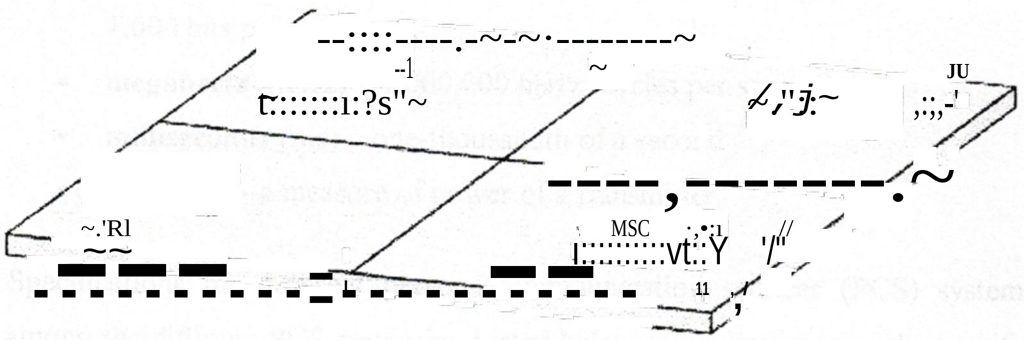
The cell is the area given radio coverage by one base transceiver station. The GSM network identifies each cell via the cell global identity (CGI) number assigned to each cell. The location area is a group of cells. It is the area in which the subscriber is paged. Each LA is served by one or more base station controllers, yet only by a single MSC (see *Figure 4.3).* Each LA is assigned a location area identity (LAI) number.

Figure 4.3 Location Areas



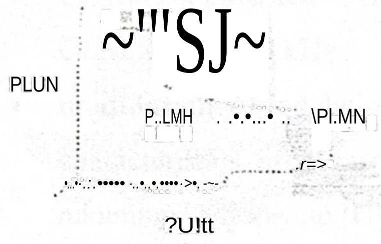
An MSC/VLR service area represents the part of the GSM network that is covered by one MSC and which is reachable, as it is registered in the VLR of the MSC (see *Figure 4.4).*

Figure 4.4 MSC/VLR Service Areas



The PLMN service area is an area served by one network operator (see *Figure 4.5).*

Figure 4.5 PLMN Network Areas



4.7 GSM Specifications

Before looking at the GSM specifications, it is important to understand the following basic terms:

- bandwidth-the range of a channel's limits; the broader the bandwidth, the faster data can be sent
- bits per second (bps)--a single on-off pulse of data; eight bits are equivalent to one byte
- frequency-the number of cycles per unit of time; frequency is measured in hertz (Hz)
- kilo (k)-kilo is the designation for 1,000; the abbreviation kbps represents 1,000 bits per second
- megahertz (MHz)--1,000,000 hertz (cycles per second)
- milliseconds (msj-e-one-thousandth of a second
- watt (W)--a measure of power of a transmitter

Specifications for different personal communication services (PCS) systems vary among the different PCS networks. Listed below is a description of the specifications and characteristics for GSM.

- frequency band-The frequency range specified for GSM is 1,850 to 1,990 MHz (mobile station to base station).

- duplex distance-The duplex distance is 80 MHz. Duplex distance is the distance between the uplink and downlink frequencies. A channel has two frequencies, 80 MHz apart.
- channel separation-The separation between adjacent carrier frequencies. In GSM, this is 200 kHz.
- modulation-Modulation is the process of sending a signal by changing the characteristics of a carrier frequency. This is done in GSM via Gaussian minimum shift keying (GMSK).
- transmission rate-GSM is a digital system with an over-the-air bit rate of 270 kbps.
- access method-GSM utilizes the time division multiple access (TOMA) concept. TOMA is a technique in which several different calls may share the same carrier. Each call is assigned a particular time slot.
- speech coder-GSM uses linear predictive coding (LPC). The purpose of LPC is to reduce the bit rate. The LPC provides parameters for a filter that mimics the vocal tract. The signal passes through this filter, leaving behind a residual signal. Speech is encoded at I3 kbps.

4.8 GSM Subscriber Services

There are two basic types of services offered through GSM: telephony (also referred to as teleservices) and data (also referred to as bearer services). Telephony services are mainly voice services that provide subscribers with the complete capability (including necessary terminal equipment) to communicate with other subscribers. Data services provide the capacity necessary to transmit appropriate data signals between two access points creating an interface to the network. In addition to normal telephony and emergency calling, the following subscriber services are supported by GSM:

- dual-tone multifrequency (DTMF)-DTMF is a tone signaling scheme often used for various control purposes via the telephone network, such as remote control of an answering machine. GSM supports full-originating DTMF.

- facsimile group m-GSM supports CCITT Group 3 facsimile. As standard fax machines are designed to be connected to a telephone using analog signals, a special fax converter connected to the exchange is used in the GSM system. This enables a GSM-connected fax to communicate with any analog fax in the network.
- short message services-A convenient facility of the GSM network is the short message service. A message consisting of a maximum of 160 alphanumeric characters can be sent to or from a mobile station. This service can be viewed as an advanced form of alphanumeric paging with a number of advantages. If the subscriber's mobile unit is powered off or has left the coverage area, the message is stored and offered back to the subscriber when the mobile is powered on or has reentered the coverage area of the network. This function ensures that the message will be received.
- cell broadcast-A variation of the short message service is the cell broadcast facility. A message of a maximum of 93 characters can be broadcast to all mobile subscribers in a certain geographic area. Typical applications include traffic congestion warnings and reports on accidents.
- voice mail-This service is actually an answering machine within the network, which is controlled by the subscriber. Calls can be forwarded to the subscriber's voice-mail box and the subscriber checks for messages via a personal security code.
- fax mail-With this service, the subscriber can receive fax messages at any fax machine. The messages are stored in a service center from which they can be retrieved by the s~bscriber via a personal security code to the desired fax number.

4.9 Supplementary Services

GSM supports a comprehensive set of supplementary services that can complement and support both telephony and data services. Supplementary services are defined by GSM and are characterized as revenue-generating features. A partial listing of supplementary services follows.

- call forwarding-This service gives the subscriber the ability to forward incoming calls to another number if the called mobile unit is not reachable, if it is busy, if there is no reply, or if call forwarding is allowed unconditionally.
- barring of outgoing calls-This service makes it possible for a mobile subscriber to prevent all outgoing calls.
- barring of incoming calls-This function allows the subscriber to prevent incoming calls. The following two conditions for incoming call barring exist: baring of all incoming calls and barring of incoming calls when roaming outside the home PLMN.
- advice of charge (AoC)--The AoC service provides the mobile subscriber with an estimate of the call charges. There are two types of AoC information: one that provides the subscriber with an estimate of the bill and one that can be used for immediate charging purposes. AoC for data calls is provided on the basis of time measurements.
- call hold-This service enables the subscriber to interrupt an ongoing call and then subsequently reestablish the call. The call hold service is only applicable to normal telephony.
- call waiting-This service enables the mobile subscriber to be notified of an incoming call during a conversation. The subscriber can answer, reject, or ignore the incoming call. Call waiting is applicable to all GSM telecommunications services using a circuit-switched connection.
- multiparty service--The multiparty service enables a mobile subscriber to establish a multiparty conversation-that is, a simultaneous conversation between three and six s;1bscribers.This service is only applicable to normal telephony.
- calling line identification presentation/restriction-These services supply the called party with the integrated services digital network (ISDN) number of the calling party. The restriction service enables the calling party to restrict the presentation. The restriction overrides the presentation.
- closed user groups (CUGs)-CUGs are generally comparable to a PBX. They are a group of subscribers who are capable of only calling themselves and certain numbers.

4.10 The Short Message Service (SMS)

The Short Message Service (SMS) allows text messages to be sent and received to and from mobile telephones. The text can comprise words or numbers or an alphanumeric combination. SMS was created as part of the GSM Phase 1 standard. The first short message is believed to have been sent in December 1992 from a PC to a mobile phone on the Vodafone GSM network in the UK. Each short message is up to 160 characters in length when Latin alphabets are used, and 70 characters in length when non-Latin alphabets such as Arabic and Chinese are used.

There is no doubting the success of SMS. The market in Europe alone had reached over three billion short messages per month as of December 1999, despite little in proactive marketing by network operators and phone manufacturers. Key market drivers over the next two years, such as the Wireless Application Protocol (WAP), will continue this growth path.

Typical uses of SMS include notifying a mobile phone owner of a voicemail message, alerting a salesperson of an inquiry and telling a driver the address of the next pickup.

4.11 Sms Technology

SMS is essentially similar to paging, but SMS messages do not require the mobile phone to be active and within range, as they will be held for a number of days until the phone is active and within range. SMS messages are transmitted within the same cell or to anyone with roaming capability. They can also be sent to digital phones from a web site equipped with a PC Link or from one digital phone to another. An SMS gateway is a web site that lets you enter an SMS message to someone within the cell served by that gateway or acts as an international gateway for users with roaming capability.

The SMS is a store and forward service. In other words, short messages are not sent directly from sender to recipient, but via an SMS Center. Each mobile telephone network that supports SMS has one or more messaging centers to handle and manage the short messages.

The SMS features confirmation of message delivery. This means that, unlike paging, users do not simply send a short message and trust and hope that it gets delivered. Instead the sender of the short message can receive a return message back notifying them whether the short message has been delivered or not.

Short messages can be sent and received simultaneously with GS~ (Global System for Mobile Communications) voice, data and fax calls. This is possible because whereas voice, data and fax calls take over a dedicated radio channel for the duration of the call, short messages travel over and above the radio channel using the signaling path. As such, users of SMS rarely, if ever, get a busy or engaged signal as they can do during peak network usage times.

Ways of sending multiple short messages are available. SMS concatenation (stringing several short messages together) and SMS compression (getting more than 160 characters of information within a single short message) have been defined and incorporated in the GSM SMS standards.

The network operator needs to purchase its first generation SMS Center as part of the network commissioning plan. The initial SMS Center may simply be a voice mail platform module or a stand-alone SMS Center. It is not possible to make the SMS available without an SMS Center since all short messages pass through the SMS Center.

4.12 Recent Sms Developments

Because simple person-to-person messaging is such an important component of total SMS traffic volumes, anything that simplifies message generation is an important enabler of SMS. Predictive text input algorithms significantly reduce the number of key strokes that need to be made to input a message. T9, from Tegic, anticipates which word the user is trying to generate. Widespread incorporation of such algorithms into the installed base of mobile phones will typically lead to an average uplift in SMS traffic of 25% per enabled user. These predictive text algorithms support multiple languages.

The introduction of standardised protocols such as SIM Application Toolkit and the Wireless Application Protocol (WAP) contribute to an increase in messaging usage by providing a standard service development and deployment environment for application developers and business partners. These protocols also make it easier for users to reply to and otherwise access messaging services through custom menus on the phone. While these protocols are only a means to an end and not new messaging destinations or services, they are likely to lead to a 10-15% uplift in total SMS volumes.

The introduction of more user-friendly terminals contributes to increases in messaging usage. Terminals such as smart phones make it easier for users to originate, reply to and otherwise access messaging services through the provision of a QWERTY keyboard, rather than the limited keypad on standard mobile phones.

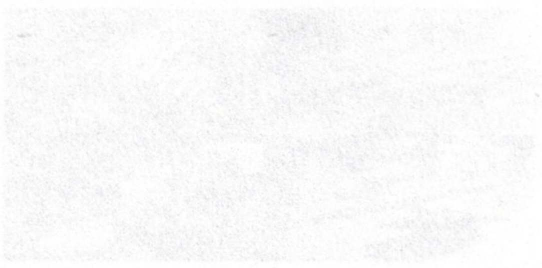
CHAPTERS

WIRELESS TECHNOLOGY

5.1 WIRELESS TECHNOLOGY

Wireless technology uses individual radio transmitters over each cell [illegible] by dividing a service area into separate geographic zones called cells. Cells can be as small as an individual building (such as an airport or arena) or as large as 20 miles across. [illegible] equipped with its own radio transmitter/receiver antenna.

Because the system operates at such a low power, a frequency being used to carry a phone conversation in one cell can be used to carry another conversation in a nearby cell without interference. This allows much greater capacity than older systems like Citizens Band (CB) in which all users must try to get their messages on the same limited channels.



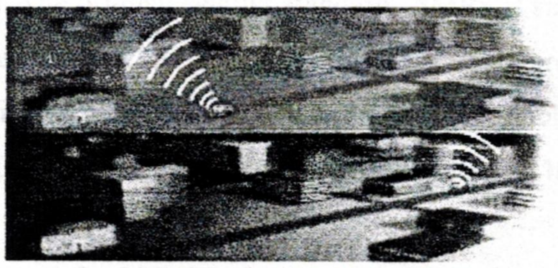
When a customer using a wireless phone – car phone or portable – approaches the boundary of one cell, the wireless network senses that the signal is becoming weak and automatically hands off the call to the antenna in the next cell into which the caller is traveling. When customers travel beyond their home geographical area, they can still make wireless calls. The wireless carrier in the area where they are traveling provides the service. This is called roaming.

Each cellular antenna is linked to a mobile switching center (MSC), which connects your wireless call to the local "wired" telephone network. Wireless carriers own MSCs.

5.1 WIRELESS TECHNOLOGY

Wireless technology uses individual radio frequencies over and over again by dividing a service area into separate geographic zones called cells. Cells can be as small as an individual building (say an airport or arena) or as big as 20 miles across, or any size in between. Each cell is equipped with its own radio transmitter/receiver antenna.

Because the system operates at such a low power, a frequency being used to carry a phone conversation in one cell can be used to carry another conversation in a nearby cell without interference. (this allows much greater capacity than radio systems like Citizens Band (CB) in which all users must try to get their messages on the same limited channels.)



When a customer using a wireless phone - car phone or portable - approaches the boundary of one cell, the wireless network senses that the signal is becoming weak and automatically hands off the call to the antenna in the next cell into which the caller is traveling. When subscribers travel beyond their home geographical area, they can still make wireless calls. The wireless carrier in the area where they are traveling provides the service. This is called roaming

Each cellular antenna is linked to a mobile switching center (MSC), which connects your wireless call to the local "wired" telephone network. Wireless carriers own MSCs.

The mobile telephone industry is limited to 45 megahertz MHz of spectrum bandwidth, which without frequency-reuse, would limit each cellular carrier to 396 frequencies or voice channels. In order to increase calling capacity, these low power facilities "reuse" frequencies on the radio spectrum. The manner in which providers organize, or "configure," their cells is an important factor in increasing frequency reuse and establishing an area's calling capacity.

- Analog cellular operates in the 800:MHzfrequency range and is available across 95 percent of the United States. Analog cellular service sends a voice through the air using continuous radio waves. As the voice signals travel through the air they get weaker with distance. Equipment in the cellular network returns the signal to its original strength, or amplifies it. This technology is the predominant system in use today. The operating system (called the air interface) for analog is called Advanced Mobile Phone Service (AMPS).
- AMPS stands for advanced mobile phone service. AMPS transmits voices as FM radio signals. The original cellular standard, AMPS is still the most widely used system in the U.S., although digital networks are catching up quickly. A variation on AMPS is narrow-band advanced mobile phone service, or NAMPS, which uses a narrower bandwidth and has greater data capabilities.
- Digital cellular shares the 800MHz frequency band with analog and is usually available where analog service is offered. In digital transmissions, a conversation is converted into the ones and zeros of computer code. Unlike analog transmissions that are sent out as a continuously varying electrical signal in the shape of a wave, digital transmissions are a combination of on-and-off pulses of electricity. Several incompatible air interfaces are used to implement digital cellular networks, including Code Division Multiple Access (CDMA) and Time Division Multiple Access (TDMA).
- CDMA is also known as spread spectrum technology because it uses a low-power signal that is "spread" across a wide bandwidth. With CDMA, a phone call is assigned a code, which identifies it to the correct receiving phone.

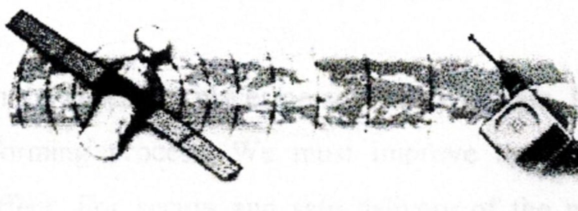
Using the identifying code and a low-power signal, a large number of calls can be carried simultaneously on the same group of channels.

- TDMA is a digital air interface technology designed to increase the channel capacity by chopping the signal into pieces and assigning each one to a different time slot, each lasting a fraction of a second. Using TDMA, a single channel can be used to handle simultaneous phone calls.
- GSM stands for global system for mobile communications. It is a type of time division multiple access (TDMA) digital wireless network that has encryption features. GSM is rapidly being deployed worldwide and is the standard in Europe at 900MHz. In the U.S., carriers are deploying GSM at 1900MHz, making GSM phones sold in the U.S. incompatible with European GSM phones, and vice versa.
- Personal Communications Service (PCS) is an all-digital service specifically designed for U.S. operations and is available in metropolitan areas. PCS is a term coined by the Federal Communications Commission to describe a digital, two-way, wireless telecommunications system licensed to operate between 1850-1990 MHz, although the FCC's rules describe "PCS" as a broad family of wireless services without reference to spectrum band or technology. PCS is capable of increased call capacity. PCS networks are CDMA, TDMA and global system for mobile communications (GSM).
- Enhanced Specialized Mobile Radio (ESMR) service is also a digital service, formed by the application of digital systems to traditional dispatch "specialized mobile radio" service spectrum, in the 800 and 900 MHz bands. By aggregating this spe~trum, and applying a cellular-like digital network, an ESMR company is able to provide a cellular- or PCS-like voice and data messaging service. NEXTEL is one such company, using Motorola's iDEN (TDMA-based) technology to deliver ESMR services in towns and cities across the U.S.

Satellite systems are another viable type of wireless telecommunications service. Instead of sending and receiving signals from a ground-based antenna, wireless phones will communicate via satellites circling the earth.

- Geosynchronous Satellites: Geosynchronous satellites represent yet another way of providing wireless communications. These satellites, located 22,300 miles above the earth, revolve around the earth once each twenty-four hours- the same as the earth itself Consequently they appear to be stationary. Communications between two places on earth can take place by using these satellites; one frequency band is used for the uplink, and another for the downlink. Such satellite systems are excellent for the transmission of data, but they leave something to be desired for voice communications. This is a result of the vast distance and the time it takes for an electrical signal to make an earth-satellite-earth round trip. That time amounts to one quarter of a second. A reply from the called subscriber takes another quarter of a second, and the resultant half a second is definitely noticeable. Consequently, voice communications is seldom carried via geosynchronous satellites

Low Earth Orbit (LEO) satellite system. LEOs are satellites that communicate directly with handheld telephones on earth. Because these satellites are relatively low-less than 900 miles-they move across the sky quite rapidly. In a LEO system the communications equipment on a satellite acts much like the cell site of a cellular system. It catches the call from earth and usually passes it to an earth-based switching system. Because of the speed of the satellite, it is frequently necessary to hand off a particular call to a second satellite just rising over the horizon. This is akin to a cellular system, except that in this case it is the cell site that is moving rather than the subscriber.



6. CONCLUSION

Information and Communication technologies begins to affect the other branches of life. Recently developed SMS technology which provide usage of WEWS technology widespread is a clear example. As Security and truthfulness of the knowledge at industrial foundations, police-traffic stations, organizations, shopping centers and at houses becomes important, WEWS applications that makes use of popular technologies seems to be necessary then ever.

Some of the areas that WEWS system can be applicable :

- Industrial Foundations,
- Electricity, water, natural gas distributor systems,
- Smart buildings,
- villas,
- shopping centers,
- houses,
- hotels,
- police-traffic stations,
- automobile industry.

At above areas important processes occur other than alarms and crashes. These are applying periodical test scenarios at fire and security systems, providing security at the energy distributor center, operating feedback systems like generator. It provides necessary profits when necessary person become aware ,of the status of these kind of processes.

Various methods are used so as to inform the necessary places/person with true data. However most of the time human does the informing process. We must improve the system by automation and remove the human effect. For secure and safe delivery of the necessary information of critical alarms, important events, summary reports (stock, product, user, organization information etc..) to the authorized person, organizations prefers WEWS system. WEWS system evaluate the signals that it takes from the automation system or organization and transfer the necessary information to the predefined mobile telephone number by making use of SMS.

General Product Description TC35

The Sıernens TC35 represents the new generatıor. of GS\1 modules ın dual band technology :.GS\.1900.'GS\~-] 800. TC35 ıs lıghtweıght and small, has optımal cower coosurnpnon ard transrmts data, voice. S\ı1S and fax. The TC35 ıs suitable for complex ınoustnat applıcauons such as ıelernetrv, telernatıcs or commurucauön. =>QS ıerrnmals and handheld devices wortdwıde wherever there ıs a GS\.1 network.

Siemens :vıll offer a correspordıngı evaluauon kıt for rapid ınter:,atıon of the TC35.
The most ırnportant features are as follovvs:

- :-requencv :.GS\.1900/GS \1' 800 ::ıhcıse 2 ı
- GS\.1 Class: Small VIS
- 2VV :,oııver for Class ,1/ :.GS\.1900
