COMPANY NAME REGISTRATION

**Graduation Project
COM400**

**Student Name : Osman Yüksel
Student Number : 20010357**

Supervisor : Mr. Ümit Soyer

Nicosia-2006

ACKNOWLEDGMENTS

First, I would like to express my deepest gratitude and appreciation to my supervisor **Mr.Ümit Soyer** for his guidance, continuous encouragement and support during the preparation of my project. At each meeting, he showed me new things about how to make an effective website. I also thank him for giving his precious time for the improvement of my project.

Finally, I would like to extend a special thank you to the Graduation Project Committee for offering me this great opportunity to prepare this project.

ABSTRACT

Nowadays, we can do all our jobs with computers using Internet. We can rent a car or a room

using Internet. Also lots of companies has their own website to inform users about their work.

So after a little search on Web, we can find any information of that company we need. This project aims to gather all information of companies and maybe other works (such as doctors) in North Cyprus in one place.

CHAPTER ONE

Company Name Registration

1.1 Introduction to company name registration

As Internet becomes a popular market, users want to get information from Internet before they buy something. So nowadays, almost all companies have at least an email address. Also some of them have their own web page.

CHAPTER TWO

HTML, CSS, JavaScript and PHP

2.1 What is HTML?

The basic language of the Internet is HyperText Markup Language (HTML). Unlike a true programming language, HTML doesn't work like an operating system and run your computer. Instead, it allows the author to "mark up" the contents of a document in order to change its visual appearance in a web browser. A browser takes the content as written in the HTML file and represents it on the screen of your computer.

HTML is designed to specify the logical organisation of a document, with important hypertext extensions. It is not designed to be the language of a WYSIWYG word processor such as Word or WordPerfect. This choice was made because the same HTML document may be viewed by many different "browsers", of very different abilities.

Thus, for example, HTML allows you to mark selections of text as titles or paragraphs, and then leaves the interpretation of these marked elements up to the browser. For example one browser may indent the beginning of a paragraph, while another may only leave a blank line.

HTML instructions divide the text of a document into blocks called elements. These can be divided into two broad categories -- those that define how the BODY of the document is to be displayed by the browser, and those that define information 'about' the document, such as the title or relationships to other documents. The detailed rules for HTML (the names of the tags/elements, how they can be used) are defined using another language known as the standard generalized markup language, or SGML. SGML is wickedly difficult, and was designed for massive document collections, such as repair manuals for F-16 fighters, or maintenance plans for nuclear submarines. Fortunately, HTML is much simpler!

However, SGML has useful features that HTML lacks. For this reason, markup language and software experts have developed a new language, called XML (the extensible markup language) which has most of the most useful features of HTML and SGML.

All HTML codes in this project are validated by online validators of W3C (World Wide Web Consortium).

2.2 What is CSS ?

Cascading Style Sheets, which is also known as CSS is a stylesheet language used to describe the presentation of a document written in a markup language such as HTML. It's generally used for styling HTML or XHTML documents. The CSS specifications are maintained by the World Wide Web Consortium (W3C). All CSS codes in this project are validated by online validators of W3C. And its recommended that CSS code is validated before release.

CSS is used by both the authors and readers of web pages to define colors, fonts, layout, and other aspects of document presentation. It is designed primarily to enable the separation of document content from document presentation. This separation can improve content accessibility, provide more flexibility and control in the specification of presentational characteristics, and reduce complexity and repetition in the structural content. CSS can also allow the same markup page to be presented in different styles for different rendering methods, such as on-screen, in print, by voice (when read out by a speech-based browser or screen reader) and on braille-based, tactile devices.

CSS information can be provided by various sources:

Author style: is the style information provided by the web page author, in the form of external stylesheets, i.e. a separate CSS-file referenced from the document embedded style, blocks of CSS information inside the HTML document itself inline styles, inside the HTML document, style information on a single element, specified using the "style" attribute.

User style: a local CSS-file specified by the user using options in the web browser, and acting as an override, to be applied to all documents.

User agent style: the default style sheet applied by the user agent, e.g. the browser's default presentation of elements.

CSS specifies a priority scheme to determine which style rules apply if more than one rule matches against a particular element. In this so-called 'cascade', priorities or 'weights' are calculated and assigned to rules, so that the results are predictable.

A simple CSS code can be like this:

```
Body{ background-color:#FFFFFF;}  
h2 {text-align: right; font-size:20; color: red;}
```

And these codes can be added to HTML file in two ways:

1. Can be added between <head> tags using <style> tag

```
<head>
  <style type="text/css">
    body { background: #fff; color: #000; }
  </style>
</head>
```

- 2 . Can be in a seperate file like style.css and can be called by <link> tag between <head> tags :

```
<head>
  <link href="style.css" type="text/css" media="screen" rel="stylesheet"
        rev="stylesheet">
</head>
```

2.3 What is JavaScript ?

JavaScript is a simple to comprehend, easy to use, general purpose scripting language. When used in conjunction with a Web browser's Document Object Model (DOM), it can produce powerful dynamic HTML browser-based applications which also can feature animation and sound.

The JavaScript language was developed by the Netscape Communications Corporation and is a trademarked name. It is a cross-platform, object-based scripting language that was originally designed for use in Netscape Navigator. Indeed, versions 2.0, and later, of Navigator can interpret JavaScript statements that are embedded within HTML code. When a request is made to see a page, the HTML code that defines the requested page along with the embedded JavaScript statements, are sent by the server to the client. Navigator interprets the HTML document and executes the JavaScript code. The resultant page is displayed for the client. It is important to understand that this interpretation occurs on the client-side rather than the server-side.

After the success of JavaScript in Navigator 2.0, the Microsoft Corporation was quick to create a clone of JavaScript, called JScript, which is a trademarked name, that is designed to run inside the Microsoft Internet Explorer. In truth, except for a few minor differences, JScript is essentially a carbon copy of JavaScript.

The latest versions of JavaScript and JScript are compliant with the European Computer Manufacturing Association's ECMAScript Language Specification (ECMA-262 standard, for short). Note that the name for this ECMA-262 language is ECMAScript. However, Netscape will continue to use the name, JavaScript and, likewise, Microsoft will continue to use the name, JScript. It is important to understand that the ECMA-262 standards sets minimum compatibility requirements. You should expect current and future versions of both JavaScript and JScript to also contain additional proprietary features, beyond the minimum requirements, designed to woo the developer to favor one language over the other. Fortunately, both Microsoft and Netscape have promised to submit new features to ECMA for inclusion in the evolving ECMA-262 standard. Many older browsers are, of course, still very happily utilizing older, non-compliant versions of these scripting languages.

2.4 What is PHP ?

2.4.1 Introduction to PHP

PHP is a scripted programming language that can be used to create websites. In early versions PHP stands for "Personal Home Page" but nowadays its short for "PHP: Hypertext Preprocessor". It is an open-source, reflective programming language used mainly for developing server-side applications and dynamic web content, and more recently, a broader range of software applications.

PHP allows interaction with a large number of relational database management systems, such as MySQL, Oracle, IBM DB2, Microsoft SQL Server, PostgreSQL, Firebird and SQLite. PHP runs on most major operating systems, including Unix, Linux, Netware, Windows, and Mac OS X, and can interact with many major web servers.

PHP provides a command line interface (CLI), as well as GUI libraries such as the Gimp Tool Kit (GTK+) and text mode libraries like Ncurses and Newt.

There's a company named Zend (aka "PHP Company") whom the PHP developers started.

As LAMP(Linux, Apache, MySQL, PHP) architecture becomes popular in Web industry as a way of deploying inexpensive and secure Web applications.

The PHP model can be seen as an alternative to Microsoft's ASP.NET/C#/VB.NET system, Macromedia's ColdFusion system, Sun Microsystems' JSP/Java system, the Zope/Python system, the Mod perl/Perl system, and more recently the Ruby on Rails framework.

2.4.2 What is server side scripting

Server-side scripts look a lot like HTML tags. However, instead of starting and ending with lesser-than (<) and greater-than (>) brackets, they typically start with <% and end with %>. The <% is called an opening tag, and the %> is called a closing tag. In between these tags are the server-side scripts. You can insert server-side scripts anywhere in your Web page--even inside HTML tags. Most popular Web scripting languages are PHP, ASP, Perl, CGI and Ruby.

2.4.3 Why PHP ?

PHP is an open source application, so you can check codes if you don't trust. And you can add extra features if you want. Also, as PHP can run on Linux and BSD based web servers, TCO (Total Cost of Ownership) decreases. And due to the multiuser architecture of these Unix based servers, it can be used with maximum efficiency. And there are millions of users, who can help you with PHP and you can find anything you find in Web with a little search.

2.4.4 What is Smarty ?

In this project Smart classes used for separating PHP codes from HTML design. So we can change the design, without any knowledge of PHP.

Smarty is a template engine written in PHP to separates PHP from HTML and is primarily used for the generation of dynamic HTML content, by allowing for the placement of special Smarty tags within a document. Allowable tags include, but are not limited to, variables such as {\$variable}, and a range of logical and loop operators.

Smarty is most often used by PHP-based applications to separate "business logic" from presentation. This makes for much cleaner coding and more flexible modification. For instance, one could typically modify a Smarty-based application's appearance (or, skin) easily, without ever looking at any business logic or PHP code.

It's an open source application and supported by PHP.net and can be downloaded from <http://smart.php.net> free of charge.

CHAPTER THREE

MySQL Database Server

3.1 What is a database ?

A database is an organized collection of data. One possible definition is that a database is a collection of records stored in a computer in a systematic way, so that a computer program can consult it to answer questions. For better retrieval and sorting, each record is usually organized as a set of data elements. The items retrieved in answer to queries become information that can be used to make decisions. The computer program used to manage and query a database is known as a database management system (DBMS). The properties and design of database systems are included in the study of information science.

The central concept of a database is that of a collection of records, or pieces of knowledge. Typically, for a given database, there is a structural description of the type of facts held in that database: this description is known as a schema. The schema describes the objects that are represented in the database, and the relationships among them. There are a number of different ways of organizing a schema, that is, of modeling the database structure: these are known as database models (or data models). The model in most common use today is the relational model, which in layman's terms represents all information in the form of multiple related tables each consisting of rows and columns (the true definition uses mathematical terminology). This model represents relationships by the use of values common to more than one table. Other models such as the hierarchical model and the network model use a more explicit representation of relationships.

Strictly speaking, the term database refers to the collection of related records, and the software should be referred to as the database management system or DBMS. When the context is unambiguous, however, many database administrators and programmers use the term database to cover both meanings.

Many professionals would consider a collection of data to constitute a database only if it has certain properties: for example, if the data is managed to ensure its integrity and quality, if it allows shared access by a community of users, if it has a schema, or if it supports a query language. However, there is no agreed definition of these properties.

Database management systems are usually categorized according to the data model that they support: relational, object-relational, network, and so on. The data model will tend to determine the query languages that are available to access the database. A great deal of the internal engineering of a DBMS, however, is independent of the data model, and is concerned with managing factors such as performance, concurrency, integrity, and recovery from hardware failures. In these areas there are large differences between products.

Oracle, MySQL, Microsoft Access, Microsoft SQL Server, Corel Paradox and PostgreSQL are the main database brands commonly used in applications.

3.2 What is MySQL ?

MySQL is a multithreaded, multi-user, SQL Database Management System (DBMS) with an estimated six million installations. MySQL AB makes MySQL available as free software under the GNU General Public License (GPL), but they also dual-license it under traditional proprietary licensing arrangements for cases where the intended use is incompatible with the GPL. It can be download from <http://www.mysql.com> free of charge.

3.3 Why MySQL ?

MySQL is a lightweight, open source application common used in Web applications. PHP is the most popular programming language used with MySQL. With PHP's MySQL integration, applications executed with maximum efficiency. And as its an opensource application so you can check codes if you don't trust. And you can add extra features if you want. And as in PHP, MySQL is multiplatform too, so you can install it on a Linux or BSD machine to decrease total cost of ownership (TCO). Lots of commercial sites like Yahoo!, NASA, Wikipedia, Alcatel used MySQL in enterprise level applications.

CHAPTER FOUR

Apache Web Server

4.1 What is Apache web server ?

Apache web server is a free software/open source HTTP web server for Unix-like systems (BSD, Linux, and UNIX systems), Microsoft Windows, Novell NetWare and other platforms.

A web server is an application which is responsible for accepting HTTP requests from clients (Web browsers), and serving them Web pages, which are usually HTML documents and linked objects like images and other media files.

Apache has a market share about %60 in Web server market. There are three more main web server application like IIS (Internet Information Services) from Microsoft, Sun

Java System Web Server from Sun Microsystems, Zeus Web Server from Zeus Technology.

Apache features highly configurable error messages, DBMS-based authentication databases, and content negotiation. It is also supported by several graphical user interfaces which permit easier, more intuitive configuration of the server.

The Apache HTTP Server is developed and maintained by an open community of developers under the auspices of the Apache Software Foundation. And it can be downloaded from <http://www.apache.com> free of charge.

4.2 Why Apache?

Apache is one of the most stable web server application in the world. And its distributed under terms of GPL License, so its an open source application. Also its multiplatform, so you can install it on any operating system and cpu architecture. As its an open source application, bug and security fixes released immediately.

CHAPTER FIVE

Content Security

5.1 Introduction to web security

The World Wide Web is expanding very quickly, with new online services bringing along new security and privacy hazards. It is virtually impossible to keep track of all the information necessary for safe surfing.

The minute you connect your computer to the Internet is the minute that the security of your data has been compromised. Even the most secure systems, shepherded by the most intelligent and able system administrators, and employing the most up-to-date, tested software available are at risk every day, all day.

Check list of minimum level security precautions:

- Make sure users understand what a good password is and what a bad password is. Good passwords cannot be found in a dictionary and take advantage of letters, numbers and symbols. Good passwords are also changed with some regularity and are not written on scraps of paper in desk drawers.
- Make sure that file permissions are set correctly.
- Make sure to keep abreast of security announcements, bug fixes and patches. For example, put yourself on a CERT or CIAC mailing list and/or return regularly to the sites which distribute the code you use.
- Attempt to crack your site regularly. Learn the tools the crackers are using against you and try your best to use those tools to crack yourself.
- Make regular backups.
- Create and check your log files regularly.

5.2 Session Management

In interaction between server and user, session management used to for keeping track of a user's activity across sessions of interaction with the computer system.

In Web applications, session management used for holding user informations, until user leaves site (close browser). As this project written with PHP, PHP session management used to keep track of user activities.

5.3 Security risks

There are basically three overlapping types of risk:

1. Bugs or misconfiguration problems in the Web server that allow unauthorized remote users to:
 - Steal confidential documents not intended for their eyes.
 - Execute commands on the server host machine, allowing them to modify the system.
 - Gain information about the Web server's host machine that will allow them to break into the system.
 - Launch denial-of-service attacks, rendering the machine temporarily unusable.
2. Browser-side risks, including:
 - Active content that crashes the browser, damages the user's system, breaches the user's privacy, or merely creates an annoyance.
 - The misuse of personal information knowingly or unknowingly provided by the end-user.
3. Interception of network data sent from browser to server or vice versa via network eavesdropping. Eavesdroppers can operate from any point on the pathway between browser and server including:
 - The network on the browser's side of the connection.
 - The network on the server's side of the connection (including intranets).
 - The end-user's Internet service provider (ISP).
 - The server's ISP.
 - Either ISPs' regional access provider.

It's important to realize that "secure" browsers and servers are only designed to protect confidential information against network eavesdropping. Without system security on both browser and server sides, confidential documents are vulnerable to interception.

5.3.1 SQL Injection

SQL injection is one of the most dangerous security problem that occurs in the database layer of an application. If you run SQL queries directly in your application, you should check if user can input illegal characters which is the incorrect escaping of dynamically-generated string literals embedded in SQL statements. It is in fact an instance of a more general class of vulnerabilities that can occur whenever one programming or scripting language is embedded inside another.

For example, if you use such a query in your application and you get \$loginUser variable from outside:

```
makeDatabaseQuery("select * from members where name= '$loginUser'");
```

In first sight, it can't be seen more dangerous. But if you give \$loginUser variable like

```
$loginUser = 'anything'; DROP TABLE members; SELECT * FROM illegalPlace WHERE name LIKE '%' as name
```

Then query above becomes like this

```
makeDatabaseQuery("select * from members where name= 'anything'; DROP TABLE members; SELECT * FROM illegalPlace WHERE name LIKE '%' as name");
```

So after this query executed, user can drop our table and can get information from another database/table we don't want.

To avoid this, the thing we should do is, escape that ' character with \'. Means that we should replace ' character in \$loginUser to \' character. There's a special function in PHP used for mysql queries, named *mysql_real_escape_string()* or *addslashes()*. So we should send \$loginUser to this function as a parameter:

```
$loginUser = mysql_real_escape_string($loginUser);
```

So user cannot crack our database using SQL injection..

5.3.2 Code execution in HTML

If you have input fields which get information from users from outer world, you should check the data gained for exceptions. For example you have a textarea in your HTML code and you want users address to be written here. But if your user inputs a php code or a javascript, your page will look different. For example if your user inputs:

```
<SCRIPT language="JavaScript"> alert('HELLO'); </SCRIPT>
```

and if you don't check this for exceptions, an alert box will appear on page. Or if user inputs a PHP code and your page executes PHP, user can do anything he/she wants to your web page.

So to avoid this, there's a special PHP function named, `htmlspecialchars()` that converts < and > chars into HTML entities like, < and > .

CHAPTER SIX

About Software

6.1 Installation

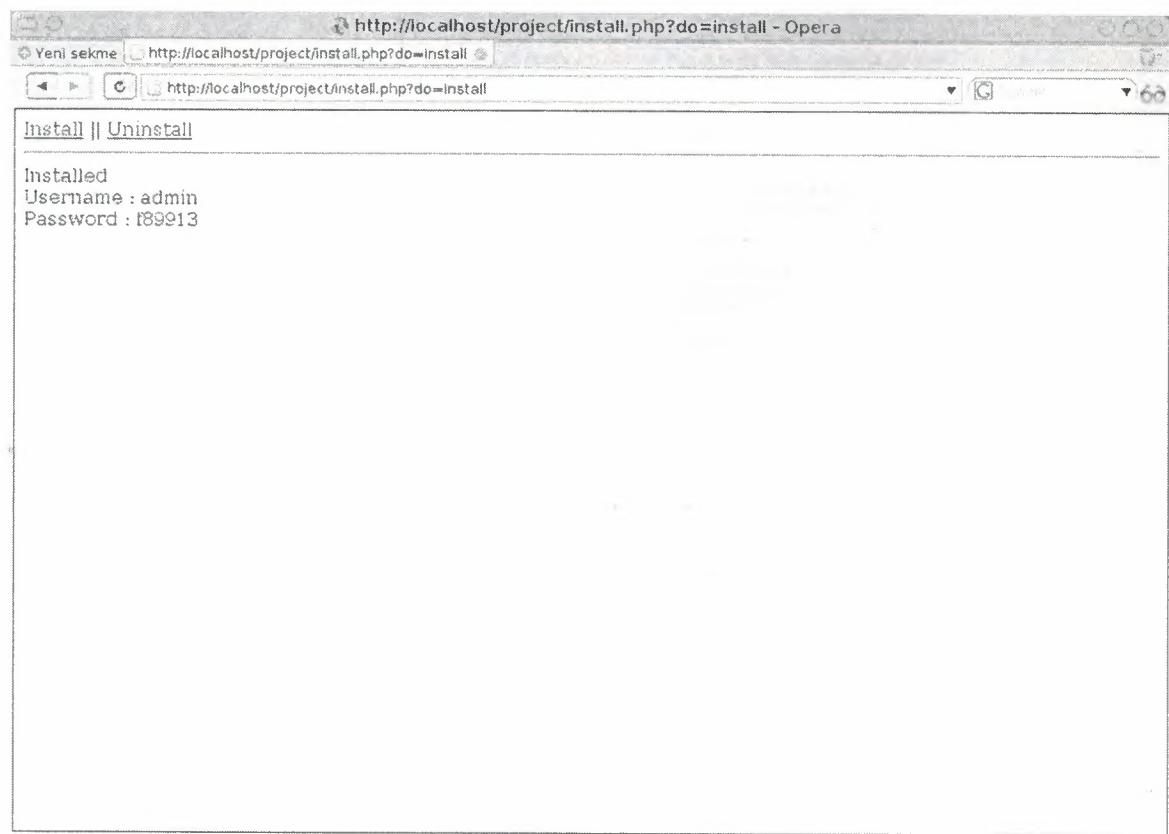

Figure 6.1 Install and Uninstall

install.php is the file where you can install and remove database tables from project with one click.

In installation, required tables created and admin user created with a random created password. These passwords are encrypted with MD5 hashes. The password created displayed on page when you install. Then you should login with this password and “admin” username from home page.

And in uninstallation all required tables and fields in this files dropped.

6.1 Homepage and links

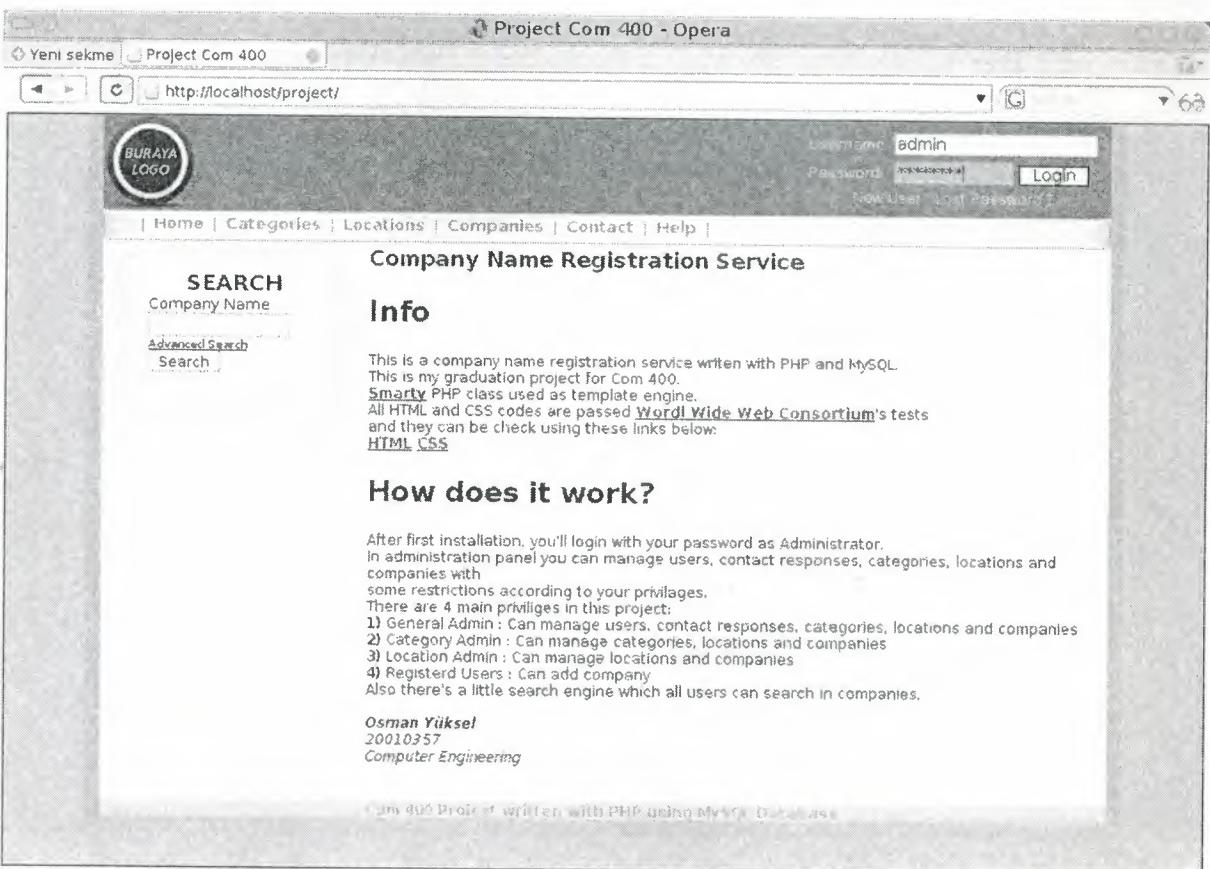

Figure 6.2 Homepage and links

In homepage there is a brief description of this project. Also there are some links where you can go to homepage named “Home”, some more links where you can list categories, locations and companies named “Categories”, “Locations” and “Companies”, a contact form named “Contact” and a documentation page named

“Help”. Also there’s a search engine at middle left, and a login form at top right which also contains new user registration and lost password actions. Also if user logged in as an admin, a notification link appears if there’s an unread contact response.

6.2.1 Home

“Home” is the link that you can return back to home page of project. In this part there’s a brief description of project.

6.2.2 Categories

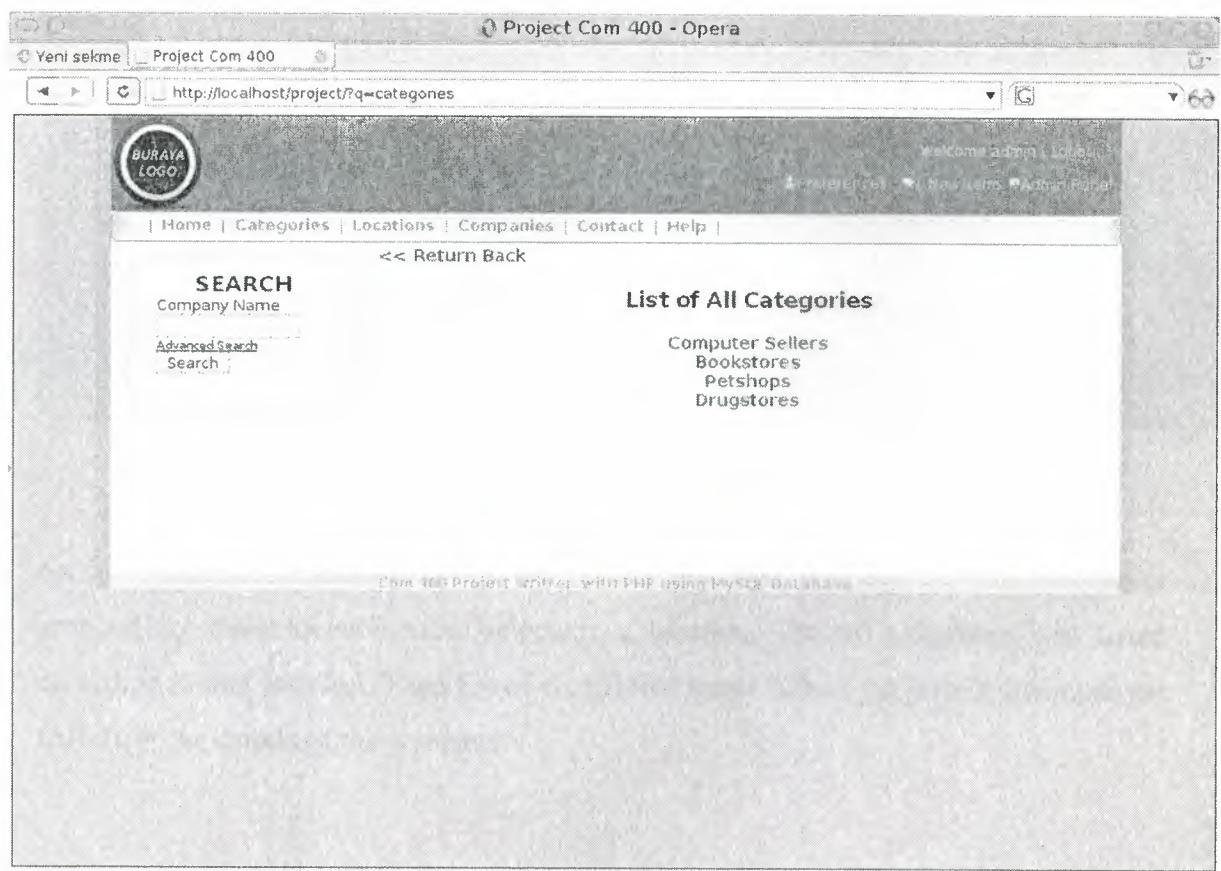

Figure 6.3 Categories

“Categories” is the link that you can list the companies grouped by their category. After selecting a category from this page companies are also grouped by their location and their category. Then found companies listed. When you select a company it will show the details of the company.

6.2.3 Locations

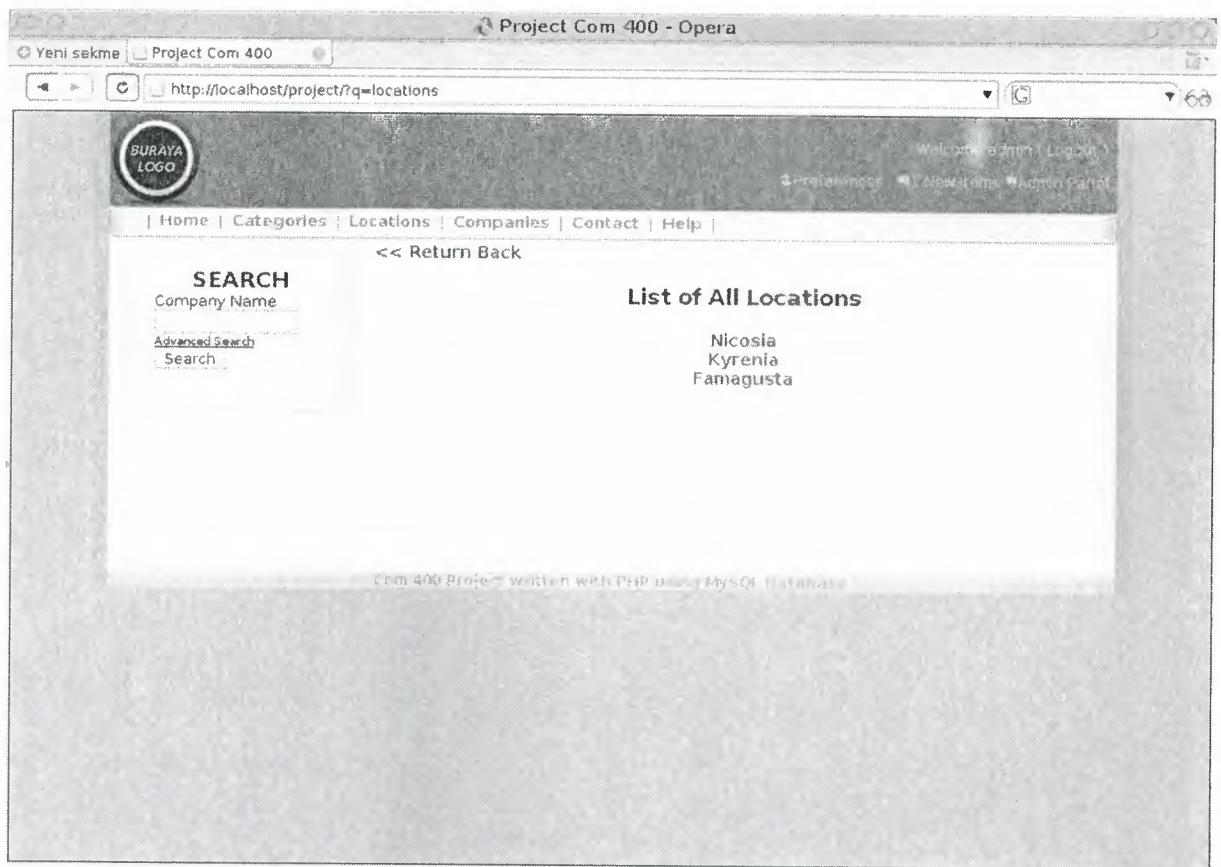

Figure 6.4 Locations

As in “Categories” section, “Location” is the link that you can list the companies grouped by their location. After selecting a location, list of categories will listed according to that location. Then list of companies listed. When you select a company it will show the details of the company.

6.2.4 Companies

The screenshot shows a web browser window titled "Project Com 400 - Opera". The address bar displays the URL "http://localhost/project/?q=companies". The page content is a list of companies under the heading "Alphabetic List of All Companies". The companies listed are:

Name	Category/Location
Bridge	
Ebim	
Güler Eczanesi	
Gürhan Kırtaşıye	
Hayat Eczanesi	
Kont hayvancılık	Petshops / Kyrenia
Mahir Bilgisayar	

The "Kont hayvancılık" link is underlined and appears to be a tooltip or a mouse-over effect. The footer of the page includes the text "Com 400 Project written with PHP on MySQL Database".

Figure 6.5 Companies

In “Companies” link, list of all categories listed in alphabetic order. And category and location of company will display when mouse is over that link.

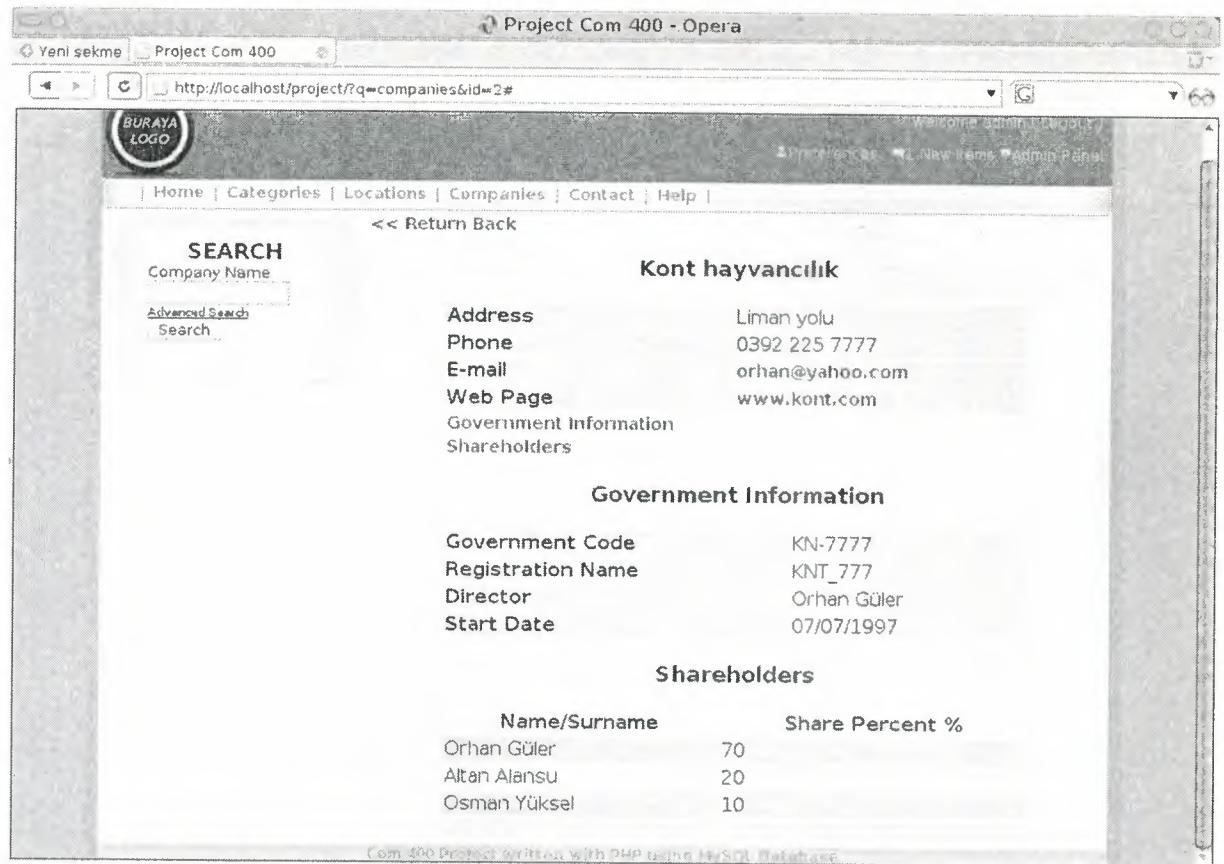

Figure 6.6 Company Details

After selecting a company from the list, details of that company displayed.

6.2.5 Contact

The screenshot shows a web browser window titled "Project Com 400 - Opera". The address bar displays "http://localhost/project?q=contact". The page content is a contact form titled "Contact Form". On the left, there is a search section with a logo labeled "BURAYA LOGO", a company name input field, and search buttons for "Advanced Search" and "Search". On the right, the contact form fields are filled with the following data:

Name:	Neşet Ertaş
E-mail:	neset@nesetertas.com
Subject:	Garip

Below the fields is a large text area containing the message "Bu iletişim formu". At the bottom right of the form is a "Send" button.

Figure 6.7 Contact Form

With “Contact” link, registered users or anonymous users can send their messages to site administrators by giving their name, surname, email address. After sending this message, administrators are able to check and reply them from using administration panel or notification link displayed top right.

6.2.6 Help

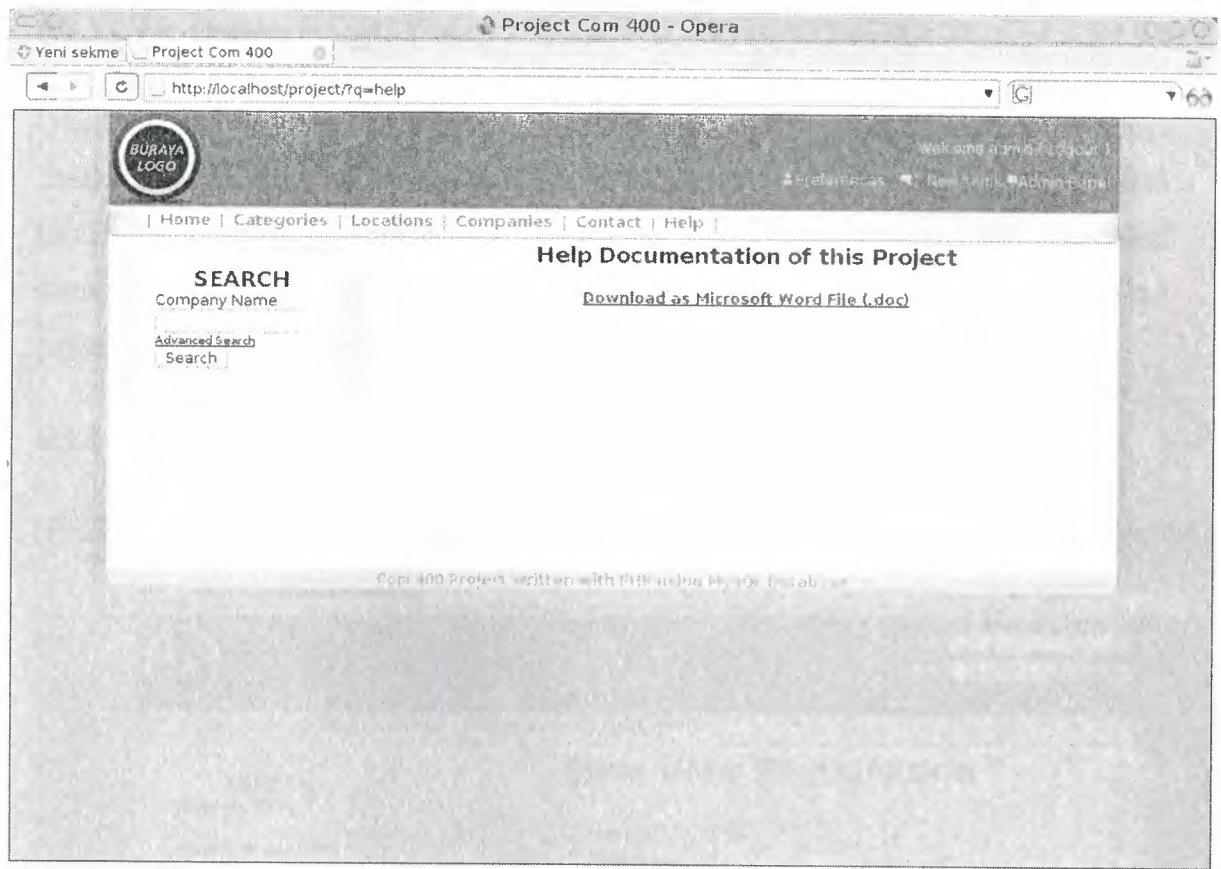

Figure 6.8 Help

In this section, users can download the documentation of this project in Microsoft Word format.

6.3 User login and registration

6.3.1 User Login

Users can log in using the login form at top right. After posting this form, a script checks that information using members table. Passwords are encrypted with MD5 hashing algorithm. So nobody can know/crack users passwords. If login succeeded some session variables set. According to that variables, user authentication defined, and pages displayed according to that authentication level.

6.3.2 User registration

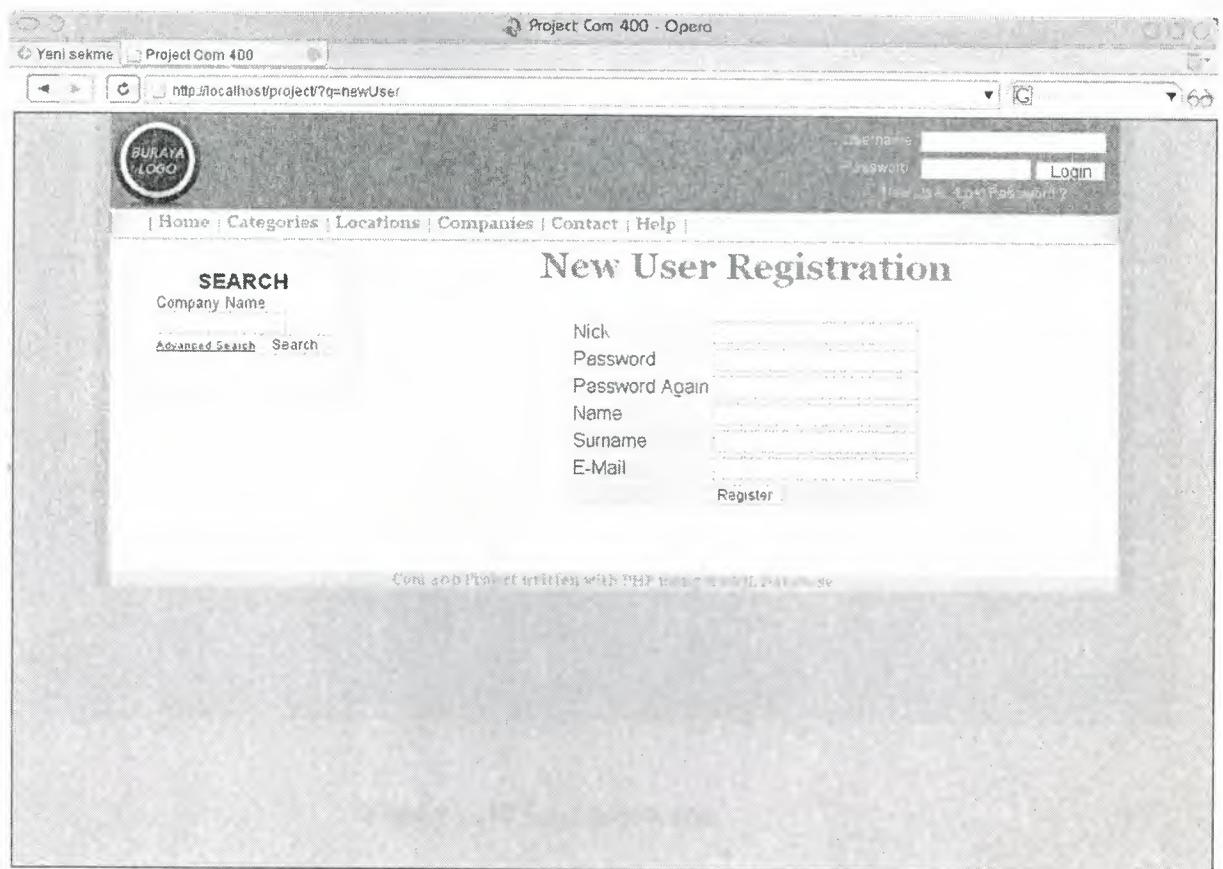

Figure 6.9 New user registration

New users can sign up using “New User” link at top right. User can create a new account with a desired nick name, password, name, surname and an email address. Script checks if user and email exists in database, and checks for a valid email. Also there are some restrictions about nickname and password lenghts.

After sending this form, registration not fully complete. An email sent to users email address. In this email there's a link for activating account. After clicking this link, form checks for activation info comes from link and activates account. Then user can log in with “Registered User” privilages.

6.3.3 Lost password

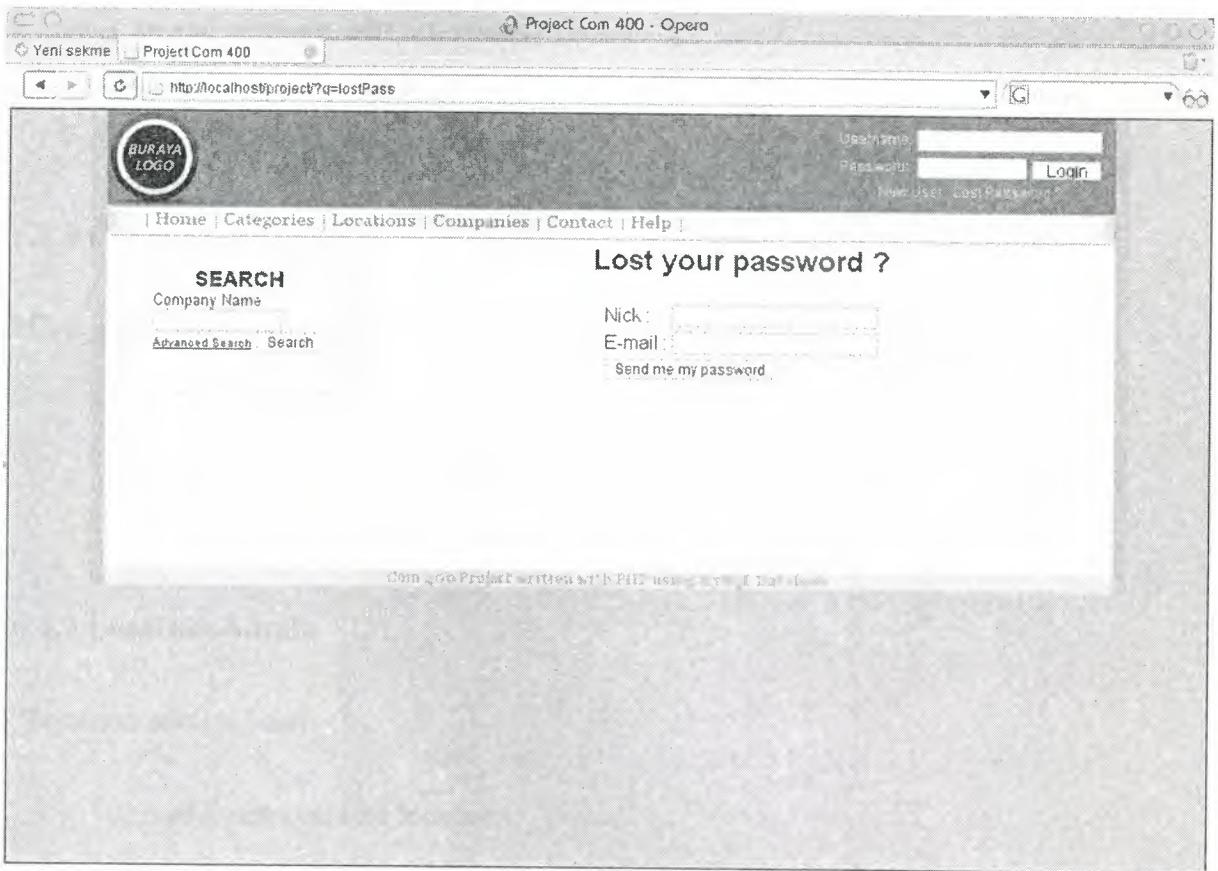

Figure 6.10 Lost password

If a user lost his/her password, he/she can get a new password to his/her email address using “Lost Password ?” link at top right. User gives his/her nick name and email address and form checks this information and generates a new password for this user. And sends these information to users email address. Then user can log in with new password.

6.4 User privilages and actions

6.4.1 General Admin

“General Admin” is the user with maximum authentication. There’s no restriction to that users. They can

- Add, remove, edit users
- Check contact responses and reply them
- Can add, remove, edit categories
- Can add, remove, edit locations
- Can add, remove, edit companies

6.4.2 Category Admin

“Category admin” is the user, who is responsible for

- Can add, remove, edit categories
- Can add, remove, edit locations
- Can add, remove, edit companies

6.4.3 Location Admin

“Location admins” can

- Can add, remove, edit locations
- Can add, remove, edit companies

6.4.4 Registered User

Registered users can only add new companies to the system. They cannot edit or remove any other component.

6.5 Admin Panel

6.5.1 Users

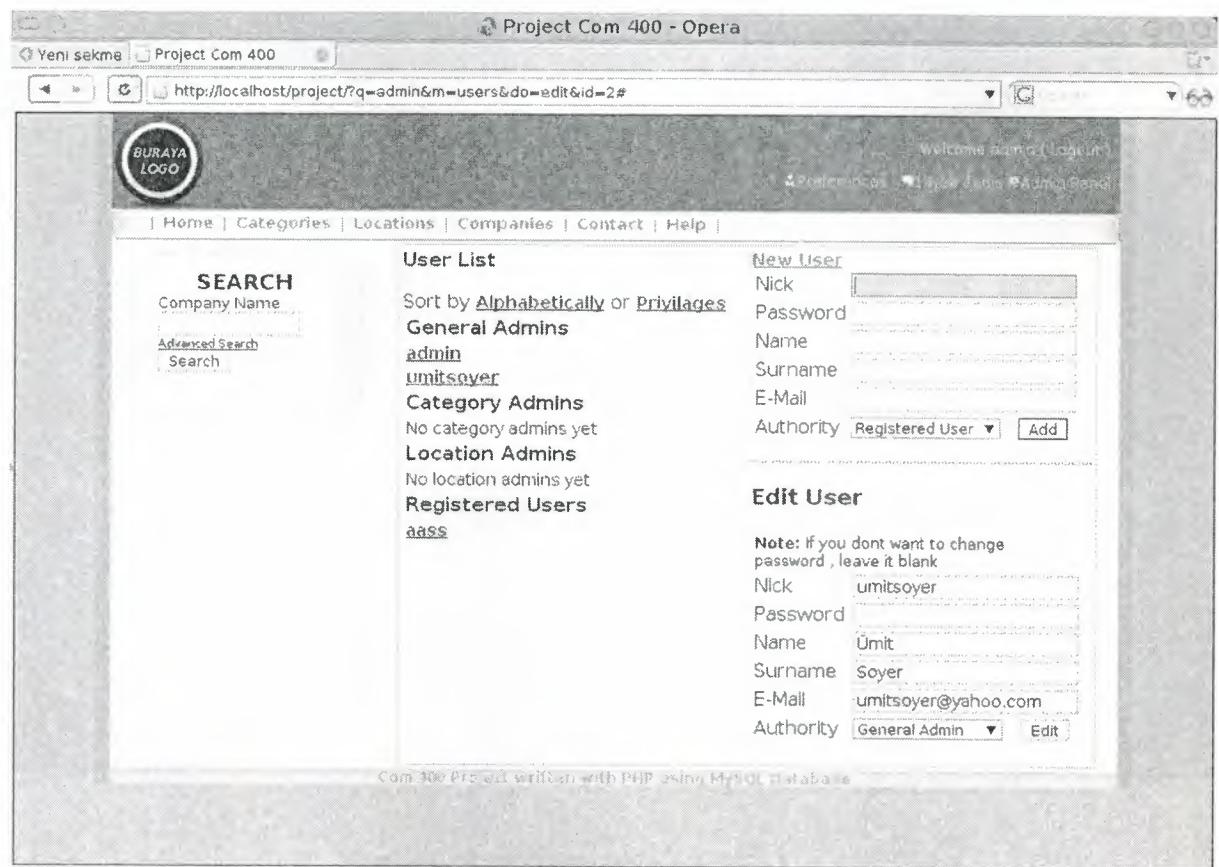

Figure 6.11 User admin panel

In user admin panel, “general administrators” can add new users or edit existing users. Users can be listed in alphabetic order or ordered by their privilages

6.5.2 Contact

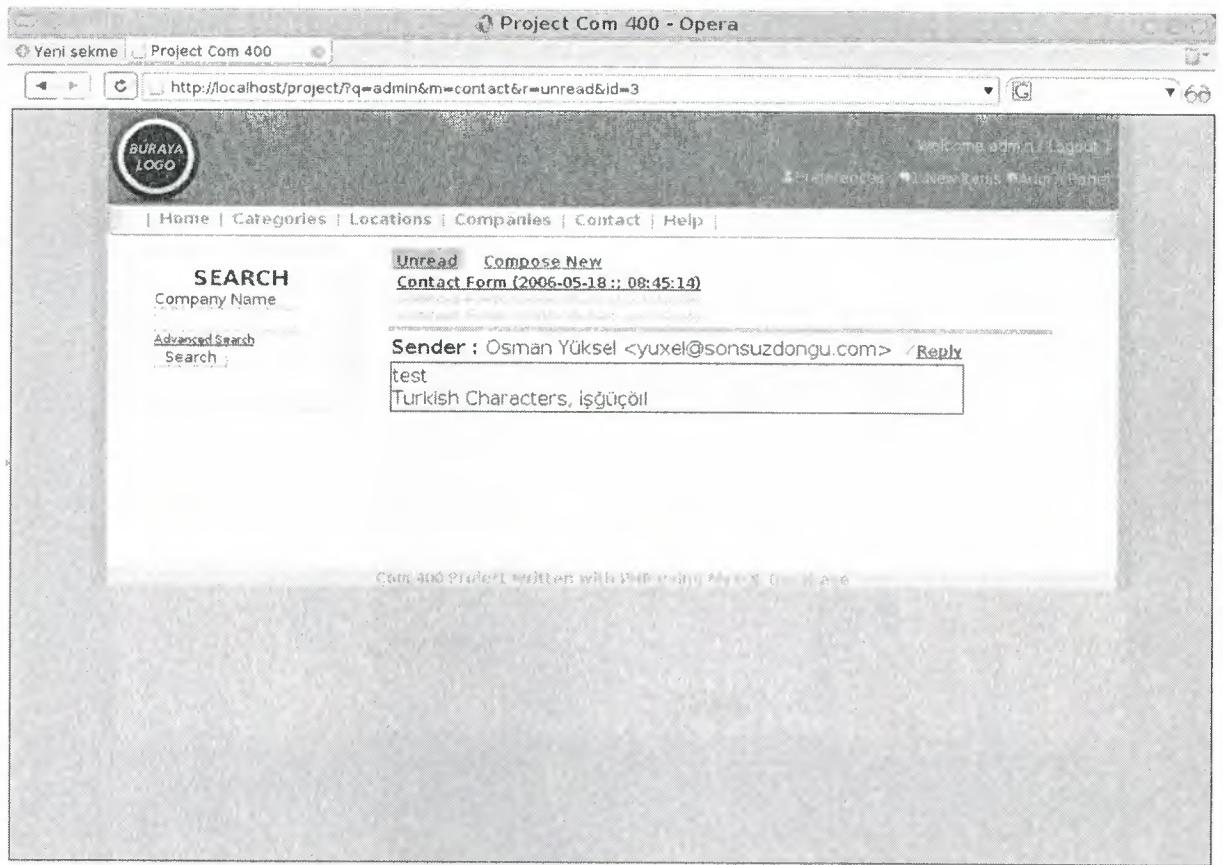

Figure 6.12 Contact admin panel

In contact admin panel, general administrators can read and reply contact responses. Also they can compose new messages to an email address.

6.5.3 Categories

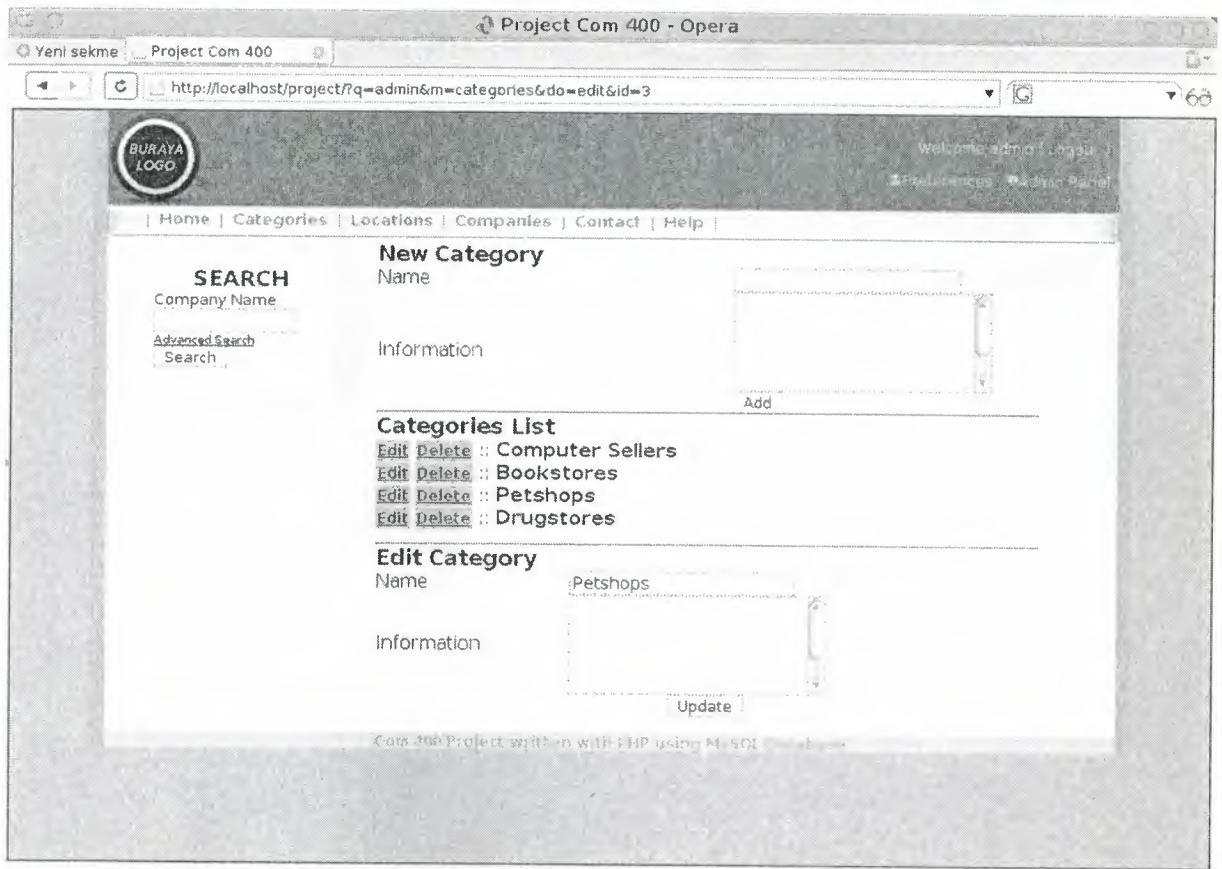

Figure 6.13 Category admin panel

Users who have privileges at least “Category admin” can add, remove or edit categories. In remove action, it checks if this category used by an existing company. If so, a warning message will be displayed to complete this action.

6.5.4 Locations

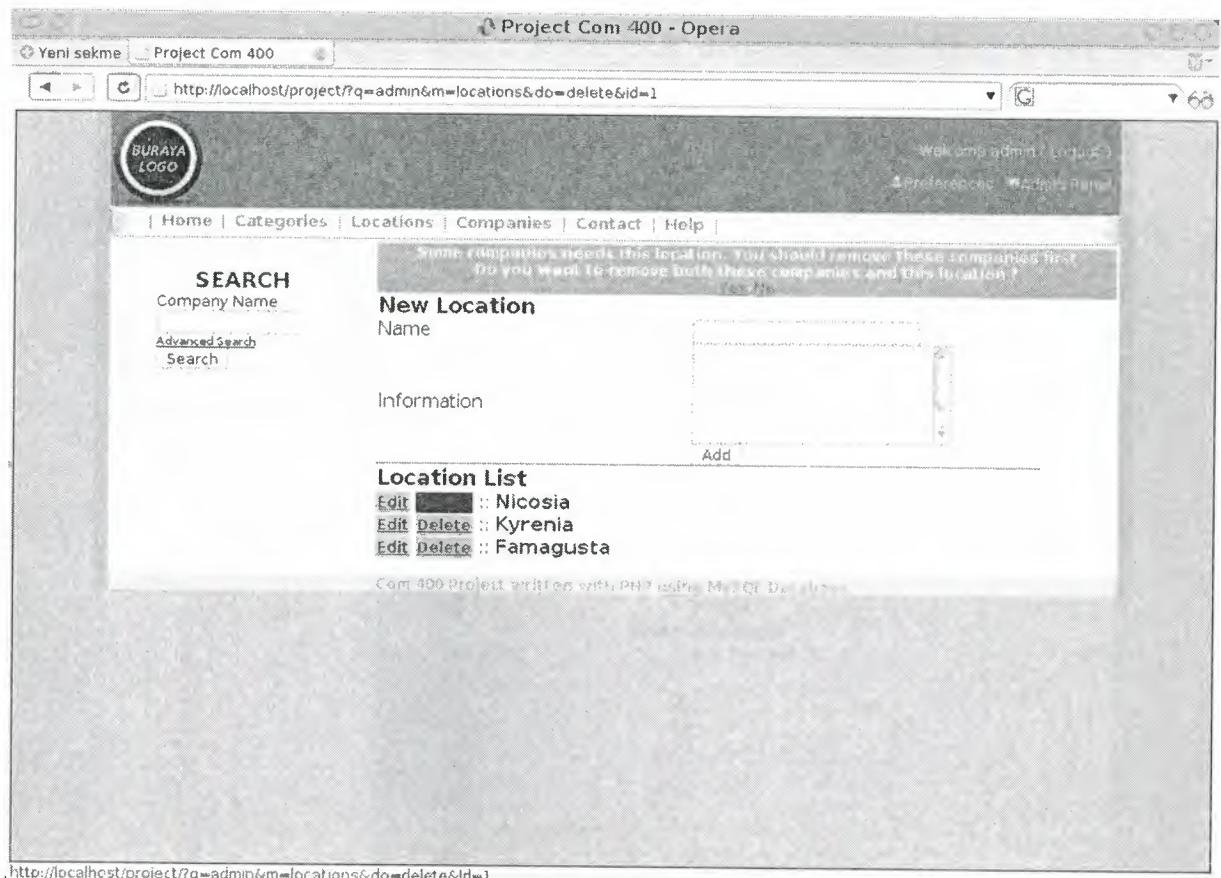

Figure 6.14 Location admin panel

Users who have privileges at least “Location admin” can access Location admin area. In this panel admins can add, remove or edit locations. In remove action, it checks if this location used by an existing company. If so, a warning message will be displayed to complete this action as seen in figure above.

6.5.5 Companies

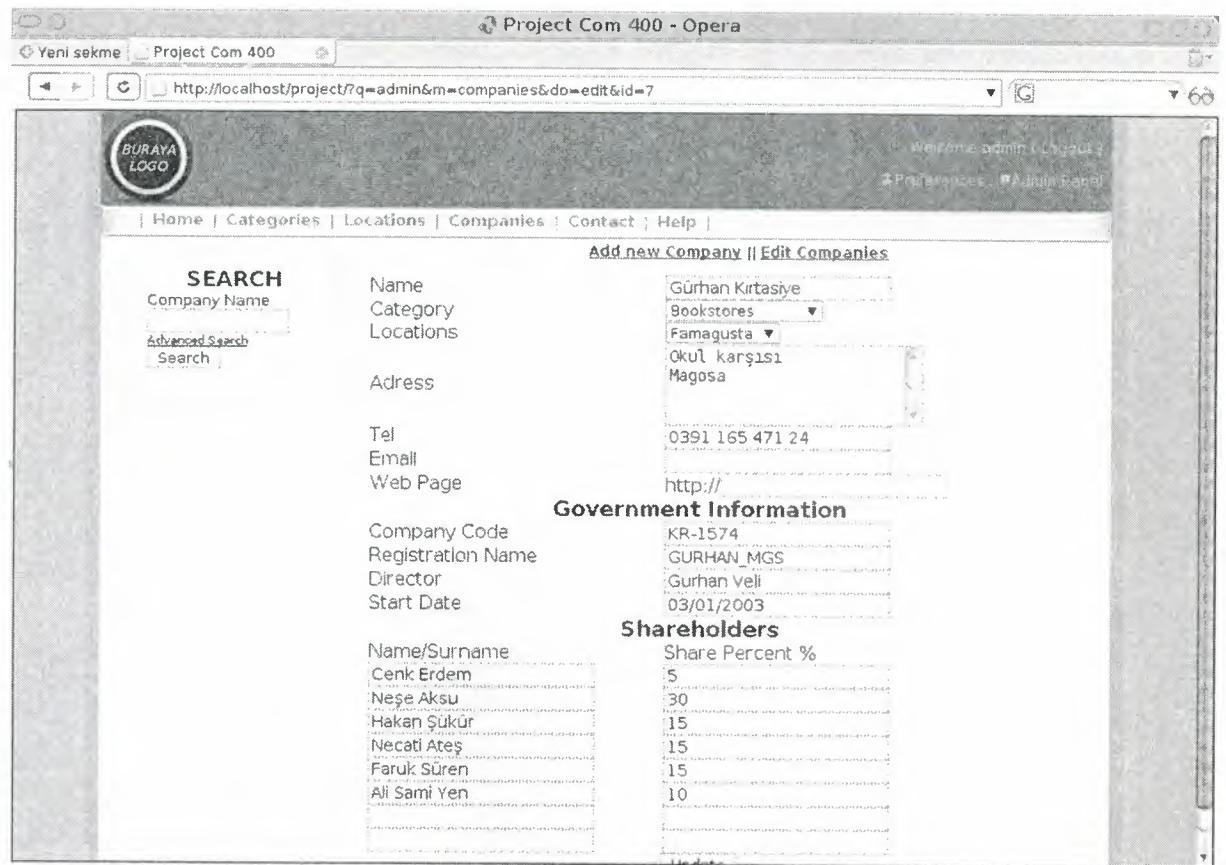

Figure 6.15 New company

All users, who has an account on system, can access this area. But users who have “Registered user” privilages can only add new company. Other users who have more authentication than “Registed users” can edit can also edit and remove companies.

6.6 Search

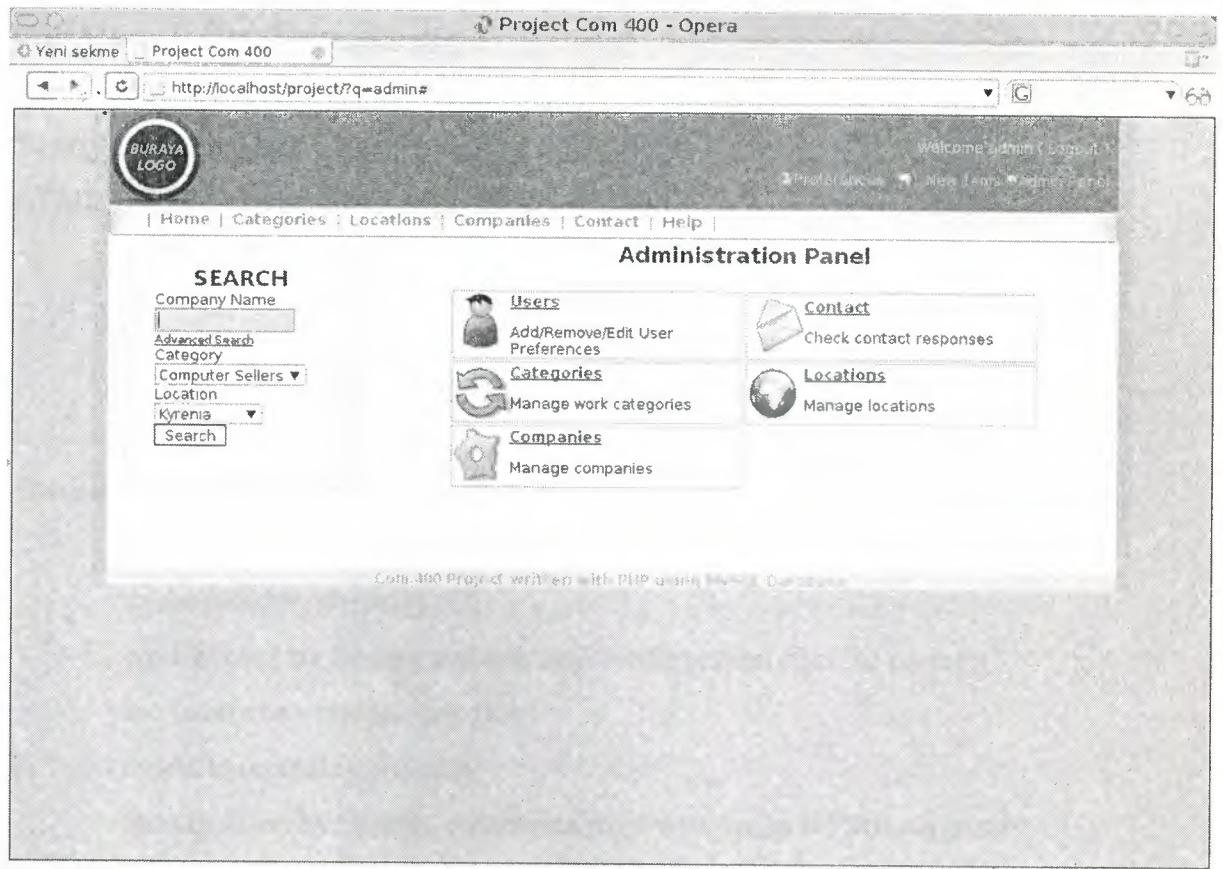

Figure 6.16 Search

All users can search companies from the search field at left. They can give a keyword for company name and they can also specify the category and location they want to search for.

CONCLUSION

The aim of this project is gathering information of companies in a single Web site. As Internet becomes popular, it becomes one of the big market for advertising. Nowadays, you can also browse the Web with your self phone. So everybody has a self phone, which has Internet access, can get information about a company using this project.

Not only for advirtesement, users can contact with companies with companies' email address or telephone number, or can search for a spesific keyword, category or location. Also this page can be easily managed by administrators using an "Admin Panel".

At last, Internet technologies develops very fast and following it is too hard. In next years, it can be seen that every job is done only using by a chip card or a mobile device.

APPENDIX A: Program Codes

There are 7 main directories in this project.

- 3rdParty (has Smarty template engine)
- cache (used by Smarty)
- config (used by Smarty and contains configuration files for project)
- inc (contains some include files)
- modules (contains modules)
- themes (used by Smarty, represents page view usign HTML templates)
- themes_c (used by Smarty, to compile theme files)

Also there are 2 main php files in this project.

- index.php (includes required files)
- install.php (installation and uninstalation)

And theese are all codes of this project.

<h3>Company Name Registration Service</h3>

<h2>Info</h2>

This is a company name registration service written with PHP and MySQL.

This is my graduation project for Com 400.

Smarty PHP class used as template engine.

All HTML and CSS codes are validated by online validators of World Wide Web Consortium

and they can be checked using these links below:

HTML CSS

<h2>How does it work?</h2>

After first installation, you'll login with your password as Administrator.

In administration panel you can manage users, contact responses, categories, locations and companies with

some restrictions according to your privileges.

There are 4 main privileges in this project:

1 General Admin : Can manage users, contact responses, categories, locations and companies

2 Category Admin : Can manage categories, locations and companies

3 Location Admin : Can manage locations and companies

4 Registered Users : Can add company

Also there's a little search engine which all users can search in companies.

For more information you can download the help document from Help page.

APPENDIX B: Database Tables

There are 6 database tables used in this project and can be seen with this command below

```

mysql> show tables;
+-----+
| Tables_in_project |
+-----+
| categories         |
| companies          |
| contact            |
| locations          |
| members             |
| shareholders        |
+-----+

```

Categories is the table which we collect information about categories. Fields of this table listed below.

```

mysql> desc categories;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra       |
+-----+-----+-----+-----+-----+-----+
id	int(10)	NO	PRI		auto_increment
name	varchar(250)	YES			
details	text	YES			
+-----+-----+-----+-----+-----+

```

Companies is the table which we collect information about companies. Fields of this table listed below.

```
mysql> desc companies;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
id	int(10)	NO	PRI		auto_increment
category	int(10)	YES			
location	int(10)	YES			
name	varchar(250)	YES			
address	text	YES			
tel	varchar(200)	YES			
email	varchar(250)	YES			
webpage	varchar(250)	YES			
governmentCode	varchar(250)	YES			
registrationName	varchar(250)	YES			
director	varchar(250)	YES			
startDate	varchar(250)	YES			
+-----+-----+-----+-----+-----+
```

Contact is the table which, contact response informations stored. Fields of this table listed below.

```
mysql> desc contact;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
id	int(10)	NO	PRI		auto_increment
user	int(10)	YES			
name_surname	varchar(250)	YES			
email	varchar(250)	YES			
message	text	YES			
is_read	tinyint(2)	YES			
subject	varchar(250)	YES			
+-----+-----+-----+-----+-----+
```

Locations is the table which we collect information about locations. Fields of this table listed below.

```
mysql> desc locations;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
id	int(10)	NO	PRI		auto_increment
name	varchar(250)	YES			
details	text	YES			
+-----+-----+-----+-----+-----+
```

Members is the table which we store information about users. In “pass” field, passwords are stored using md5 encryption method. Fields of this table listed below.

```
mysql> desc members;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
id	int(10)	NO	PRI		auto_increment
nick	varchar(250)	YES			
pass	varchar(20)	YES			
name	varchar(250)	YES			
surname	varchar(250)	YES			
email	varchar(250)	YES			
auth	tinyint(2)	YES			
is_active	tinyint(2)	YES			
activation_code	varchar(20)	YES			
+-----+-----+-----+-----+-----+
```

Shareholders is the table which we store information about shareholders according to their company. Fields of this table listed below.

```
mysql> desc shareholders;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
id	int(10)	NO	PRI		auto_increment
company	int(10)	YES			
name_surname	varchar(250)	YES			
percent	varchar(10)	YES			
+-----+-----+-----+-----+-----+
```
