**Graduation Project  
COM – 400**

**Student : Kaya TAŞKAYA**

**Supervisor : Mr. Ümit İLHAN**

**Nicosia - 2002**

## ACKNOWLEDGMENTS

All our thanks to those who endlessly encouraged us through out our undergraduate studies and provided us with all kind of support financially or moralling. Who stands beside us at every moments of our life, Our Parent? Felling proud to decicate this Project for them together with our respectful brother Can ARSLAN and Nail ER.

We would like to Express our faithful thanks to our University with all its education staff and our instructors who have been a good guide for us, specially our supervisor Mr. Ümit İLHAN who provided us with valuable advises and help to achieve our graduation Project besides being an example of the responsible teacher.

Thanks to all our friends and school mates who joined us and shared our work sportingly.

## ABSTRACT

I have conducted this project using ASP (Active Server Pages) technology. The web site introduced in this project is a web site of a small bank. On those pages, normal banking customers can have membership to the online banking and transfer money to the other customers in the bank. Also it contains a section where users will be informed about the latest exchange rates.

This web site is administrated and maintained by an authorized administrator where they have been granted with a password access to the administration page. Those administrators have rights to see the all transactions and the comments sent by the customers.

Also, a program has been developed with Microsoft Visual Basic in order to view all the user transactions and comments where this program will run on the server side of the system.

## - What is an ASP?

Application Service Providers (ASPs) are third-party entities that manage and distribute software-based services and solutions to customers across a wide area network from a central data center.

In essence, ASPs are a way for companies to outsource some or almost all aspects of their information technology needs.

According to ASPnews.com, ASPs are broken down into fine subcategories:

- Enterprise ASPs – deliver high-end business applications.
- Local/Regional ASPs -- supply wide variety of application services for smaller businesses in a local area.
- Specialist ASPs – provide applications for a specific need, such as website services or human resources.
- Vertical Market ASPs – provide support to a specific industry such as healthcare.
- Volume Business ASPs – supply general small/medium-sized business with prepackaged application services in volume.

In detail, ASPs represent a new global industry devoted to reliable, predictable and efficient delivery of advanced application services to a broad range of businesses and individual consumers. An Application Service Provider (ASP) offers access to applications, as well as the associated IT infrastructure and support services, to customers on a subscription basis. ASPs host applications at a remote data center and deliver them to customers over private networks or the Internet. There are many types of application service providers. Some focus on augmenting in-house enterprise IT professionals with best practices, such as document management; while others provide enterprise-class software services to small- and medium-sized organizations; still other ASPs offer specialist software packages to vertical markets, such as education, manufacturing, or healthcare. Typically, the ASP charges the end-user organization a fixed, monthly fee based on application usage and services rendered, such as additional requirements in hardware, service and support, maintenance and upgrades. ASPs share several characteristics:

**ASP provides typically encompass the following application services:**

- Access - Analogous to "pay-per-view" television, ASPs deliver application access to users on demand for a fee, allowing the customer to use the application without having to license, maintain or support it.
- Infrastructure operations - ASPs operate the data centers where applications are hosted, providing software management, security, and disaster recovery, and business functions such as billing and usage monitoring.
- Network connectivity - These services, often delivered in partnership through local telecommunications firms or Internet Service Providers, may include connections to the Internet, operation of a Virtual Private Network, and reliability, performance and security management.
- Support services - The ASP provides end-user helpdesk support and training services surrounding the application's use.
- Management service - Applications are hosted and managed at a central site, rather than each customer's site, and delivered to users in remote locations. This includes daily administrative tasks associated with running applications as well as managing upgrades and updates.

**There are several types of applications are available through ASPs:**

Virtually any application can be delivered through the ASP computing model.

Application services range from the most complex enterprise resource planning (ERP) systems, customer relationship management solutions and vertical applications, to basic groupware, personal productivity suites, and full desktop and printing services.

Applications enable organizations to generate revenue, offer new and better services, increase levels of user knowledge, and enhance overall productivity. Organizations can extend the reach of business applications whenever and wherever they're needed.

- Generate revenue through new sales vehicles such as e-commerce and customer resource management (CRM), to customer billing and sales force automation applications.

- Provide better customer service through online ordering/tracking and customer self-service, to call centers, order entry and help desk applications.
- Enhance organizational knowledge through intranets, email and groupware that streamline communications and collaboration, to data warehousing, data mining and decision support solutions.
- Increase user productivity through personal productivity suites and contact management, to enterprise-class ERP and supply chain optimization applications.

**- What are the strength and weakness?**

**The Strength:**

- **Simplicity** – ASP provides application rental which can solve any kind of need. With customized application, user can focus on his own business without spending time on IT.
- **Speed** – Whenever there's a problem occurs, the ASP can fix the problem immediately. Unlike the traditional way which companies buy software and install locally and if anything goes wrong, they have to call the software provider to send out technicians for service.
- **Up-to-date** – With ASP, the implementation of application is fast and performance is always optimized because ASP maintains clients whole database.
- **Customization** – ASP can provide the application only for client's need.
- **Scalability** – With the customize application, ASP can low down the cost of a new application without buying a whole package of software like before.

**The Weakness:**

- **Lack of popularity** – With the popular use of Window based software, companies from small to middle size have not idea of existence of ASP technology.
- **Bandwidth of network** – With the subscription of ASP service, users need to have network connection in order to use all the applications. But since there are some bottlenecks with internet infrastructure, to fully use the ASP service is not possible.
- **Data security and privacy** – How to prevent the ASP server been access unauthorized and privacy between customers will become a very important issue

when ASP service becomes more and more popular. There still has no complete regulation of this kind of issue since this is a new area of business service.

### **- What is the future of ASP?**

Although the information technology revolution has created a profound impact on business and a certain segment of consumers, a persistent issue remains  $\frac{3}{4}$  its unavailability to the vast majority of the world. Information "have-nots," estimated at 95 percent of the world's population, are barred from participation through cost, complexity and lack of access. The rise of "rental" applications and the development of simple, inexpensive information appliances promise to break down the walls between the information "haves" and "have nots."

These two trends go hand-in-hand to deliver ease-of-use, low-cost and reliable information access to consumers, small businesses and other groups that lack the resources to implement personal or business computing solutions. Application service providers have the potential to make applications as easy, inexpensive and fast to obtain as "pay-per-view" television programs, cable packages or phone services, such as call waiting or voice mail. Users are spared the cost and difficulties of licensing, installing, upgrading and maintaining their own software, or paying for PCs to run it on.

The other half of the solution, information appliances, will be instrumental in delivering on the promise of the "information revolution." Simple, reliable fixed-function devices - which may include cellular phones, information kiosks, set-top boxes and terminals - contain no moving parts to modify, replace or upgrade because all application functionality is based on a central server and delivered via server-based computing technology over cable, phone lines, etc. Accessing an application will be as simple as turning the device on and pushing a button or two.

Application Service Providers provide a bridge to the future of computing by transforming the network into the heart of the system and the client into a simple device that is as interchangeable and maintenance-free as a telephone. The result is a new paradigm of ubiquitous computing that breaks the cycle of upgrades, provides high-performance access to thousands of new and existing applications, and reduces cost and

complexity so that more people and organizations can reap the benefits of information technology. What does the future look like?

### **What does the future look like?**

- At home, you'll use simple screenphones to access home banking and ATMs from a central server farm residing in the ASP data center. You'll be able to download electronic cash to your credit card, access your financial information, pay bills, and make stock transactions. In addition, home network terminals and television sets will be connected to extensive information services. Communication, education, shopping, and entertainment will be available, at your fingertips, 24-hours a day. The home will be "appliance-enabled," with single-purpose information appliances to serve the needs of anyone, anywhere.
- Mobile service workers will use multi-functional, wireless information appliances to communicate with other service personnel. They will be able to access repair manuals, review service records, and check parts inventories using applications delivered via the ASP data center. Customers will get better, faster service, and their service providers will get a competitive edge.
- Educators will be able to focus on teaching again, instead of managing computing environments. Students, teachers and administrators will all be connected to application service centers that offer the latest software programs, education information and learning resources, whether at school, on a field trip or right at home. The power of computing will at last be available to everyone - regardless of socio-economic status or school location.
- Information appliances in your automobile will update you on traffic conditions, help you navigate, allow you to review entertainment options, restaurants, shopping, hotels and more - all while you are on the road. Every new function will be delivered, managed, monitored and billed from the server.

### **- How does ASP work?**

#### **The Application Hosting Ecosystem**

The application hosting ecosystem is made up of application service providers (ASPs), network service providers (NSPs) and application specialists. Each member is integral in providing the complete customer solution.

### **The ASP Value Chain**

#### **Delivering a Better Business Solution Through Partnering and Core Competencies**

Application service providers are emerging as an active, on-line applications channel that is altering the technology industry's commercial practices for selling software products and services. The application hosting model combines an ASP data center, the bandwidth of a Network Service Provider (NSP), the application-specific expertise of consultants, value-added resellers, system integrators and independent software vendors (ISVs) with enabling infrastructure technologies, such as Citrix MetaFrame application server software, to extend best-of-breed solutions to the end-customer.

Because there are many starting points from which to enter this market, a wide range of companies are building full application hosting solutions by enlisting partners to complement their core competencies. An organization may choose to play one, two or all three roles, depending upon its core competencies, business objectives and capital resources. Some ASPs have the internal resources to provide all application delivery services, while others work with complementary partners such as network service providers and application specialists to deliver a complete solution. In some cases, an Independent Software Vendor may act as an ASP to target new markets for its software by partnering with providers of delivery, network management and support services. Behind the seamless and transparent delivery of application services to customers, lies a complex weave of back-end partnerships and infrastructure.

### **Potential Bottlenecks of the Current Technologies**

#### **Network Bandwidth**

The Internet has been growing tremendously since 1995, when the WWW starts to penetrate the general public. However, the global and national network infrastructures

still have a long way to go, before the current bandwidth issues are resolved. Even though more and more high-speed connections (such as DSL and Cable Modem) start to appear in households, most home users still use 56K dial-up connections to get on the Internet. Moreover, Wide Area Network (WAN) connections can often be the bottlenecks to fast connection from two distant points on the Internet. Even if the connections are fast for both the ASP's and their clients, if the links between them are slow, the applications would still suffer. Therefore, ASP's try to get around the bandwidth problems by making the web applications as slim and fast as possible, while requiring the least bandwidth. Companies like Citrix and SCO both have their own thin-client solutions that leverage the web. Citrix's product Metaframe allows running of windows applications from remote, using thin-clients such as hand-held devices, Unix, and Java-enabled browsers. SCO's Tarantella has similar technologies, but it is available for both Windows NT and Unix platforms. Both of them web-enable existing applications and provide universal access to a variety of clients. However, both companies are still striving to make their technologies as light as possible, in order to be less affected by network bandwidth issues we are still facing today.

## **Security Issues**

**Data security.** Housing your applications remotely at a vendor's data center and accessing them over the Internet raises justifiable concerns about the security and privacy of sensitive corporate data. To address these concerns, leading ASP's use a number of security measures to safeguard their customers' data, including:

- o Encryption of data over the network . If data is not encrypted, passwords and sensitive data (such as credit card numbers and financial information) can be captured (through a network sniffer, for example) by malicious attackers, who can then engage in criminal activities based on the captured information.
- o Authentication of users. This is to ensure that access of the application is only available to intended users.
- o Access control to ensure users can only get specified information. Based on the roles of the users, each person gets different access level to the application and the data.

- o Use of Virtual Private Networks, firewalls, intrusion-detection software. This is to further safe-guard the application and the data. Intrusion-detection software can detect potential threats of intrusion, by recognizing port-scans and probe patterns.
- o Dedicated servers and hardware for each customer or special software to protect access in a shared-server environment. In a shared-server environment, different customers might accidentally come upon each other's data, due to mis-configurations on the server and bugs of the application.
- o Written policies and procedures. Strict policies should be set so that both the ASP's and their customers understand that there are rules to be followed and enforced, in order to achieve the highest security of the software and data.
- o Security audits. Auditing and analyzing of security and system logs can reveal potential threats and attackers. Unknown and foreign connections to any service should be watched closely to sort out real threats from malicious attackers from random probes by harmless kids or students.
- o Data backups. Backups should occur regularly and frequently. In addition, off-site backup is a must for mission critical applications, in order to protect from natural disasters such as earthquakes, fires, etc.
- o Disaster recovery plans. In order to appropriately handle natural disasters mentioned above, precise steps for damage control and recoveries need to be firmly established long before it happens. Even though the chance of it happening might be slim, if recovery plans are not in place, disasters can lead to further destructions of the ASP's and their customers.
- o Background checks on employees. Employees need to be hired with caution, because unethical ones can always do great damage to both the ASP's and their clients, if they have easy access to their application and data.

**Loss of control:** Turning applications, service and support over to an outside provider can make companies anxious about losing control of vital business solutions and IT quality. According to a recent Zona Enterprise Usage Study, a highly rated issue was concern about whether the ASP has the proper skills to implement and deliver applications. And because the ASP industry is a young one,

there may be questions about the long-term viability of the provider. Following are safeguards customers and ASPs can implement to ensure confidence in the solution:

- o Guaranteed response times spelled out in SLAs. This way, both the ASP's and their clients have a clear understanding of the turnaround time for response and leave no room for dispute, in case of any problem.
- o Escalation procedures for problem resolution. Escalation ensures that appropriate parties are involved in the right sequence to resolve the issue quickly.
- o Written transfer plan to provide continuous service in the case of ASP business failure. This gives the clients confidence that their services will not be disrupted in the case of a bankruptcy of their ASP's.

## **Conclusion**

As the Internet Infrastructure improves nationally and globally, bandwidth should be less and less of an issue. High bandwidth connections are not just available to the government, ISP's, corporations, schools, etc, but also to home users, who can now enjoy high-speed web surfing via DSL and Cable connections. In addition, with more and more network infrastructure in place and more and more people adopting DSL and Cable lines, the price of a high-speed connection will drop to a very reasonable and affordable range. Even the current price range of about \$40 to \$50 for a DSL or Cable line is relatively inexpensive and it will only get better.

Security, which TCP/IP was not originally designed for, but rather for functionality and efficiency, is now one of the most discussed and researched topics in the computer industry. The next version of Internet Protocol (IPv6) will have security features built into the protocols and applications will definitely benefit tremendously from this improvement. At present, if confidentiality and data integrity need to be guaranteed in a network application, encryption schemes (both symmetric, which has the same key for encrypting and decrypting, and asymmetric, which has different keys for encrypting and decryption) and hash algorithms are used, as seen in HTTPS, SSH, and SSL.

Ubiquitous access to a mission-critical application for a company or an institution can easily be achieved if the application is web-based. However, hosting a web-based application involves lots of issues, including the major two mentioned above.

## CONCLUSION

I have used ASP technology in order to accomplish this project. The most important aspect of ASP is database management.. All the information and transactions of the member customers have been saved to a database for later processes and references. Also this project guided me to improved my scripting and HTML knowledge.

While designing web interfaces with third party programs such as FrontPage and Dreamweaver that necessarily do not need programming background, but integrating ASP to the HTML codes requires a scripting and background knowledge that leaded me to improve my scripting knowledge in web programming.

The most important reason that ASP appealed me is that it is a key to the future while Internet is spreading in every segment of life and millions of people are getting online every day.

In this project, I have established the the fundamentals of ASP and I will be happy to use it in my professional life.
